In regard to the cause of the disease, I have nothing to offer. It presents many of the qualities of an infectious nature. I have not as yet been able to discover any proof of contagion. I have, however, from time to time, observed it affecting two or three children in one family, but have never observed it in the form of an epidemic. In regard to the comparative frequency with which it affects the sexes, I have seen it more often in males. Terson (*Annales d'oculistique*, November, 1902) states that in the cases that he observed 85 per cent. were in males.

The disease affects both eyes almost without exception. I have seen involvement of the cornea in some cases, particularly those in which vegetations occur.

As to pathology: vernal conjunctivitis differs from trachoma in that the retrotarsal fold never presents vegetations; in fact, it does not appear to be involved, if we except some slight swelling. The minute papillary elevations which occur present a character entirely different from the trachoma follicle. They may be likened to the pile of velvet, perhaps a trifle coarser and shorter. This condition persists in a modified manner throughout the months of quiescence. After some years the papillæ become more or less aggregated and form fungoid elevations. These elevations under the microscope show a condition resembling fibrous papillæ. In some the sections show a great deal of fibrous tissue, the epithelial cells dipping down into it; in others the papilliform arrangement is more marked. The fungoid masses may be very few in number, scattered over the tarsal conjunctiva of the upper lid, or they may be quite numerous and involve the tarsal conjunctiva of both lids. It is at this stage that corneal complications are prone to occur. In this and the early stage a scanty, tenacious, muco-purulent secretion is present. The hypertrophied pericorneal tissue may encroach on the cornea, leaving on subsidence an irregular, opaque annular ring which may reach 2 mm. in width. I have never seen it extend over the entire cornea.

In the treatment of this condition I have found that mild measures serve best. Bathing the eyes with a warm solution of boric acid twice daily and the introduction of a 1 to 1.5 per cent. ointment of the yellow oxid of mercury into the eye once daily, at night, serve to reduce the inflammatory phenomena and to bring about a favorable condition. It has also been my habit to dust calomel on the conjunctival surface after everting the lids, perhaps every second day, putting on a very thin layer of calomel. The fungoid masses may be excised, but they are pretty sure to return in a very short time. However, if they are causing much irritation to the cornea, they should be excised. An attempt to change somewhat the nutrition of the conjunctiva by compressing it between the blades of trachoma forceps is sometimes of service. On the whole, however, mild treatment results in the greatest good to the patient. In regard to the use of cocain, I would say that in my hands it has not been beneficial. The congestion that follows often prolongs the disease.

Dr. Henry Dickson Bruns, New Orleans—In our clinics in this city I have had a good opportunity of comparing diseases of the eye as they exist in the white and negro races. I have just finished the study of 17,000 odd cases, of which 36 per cent. were negroes. Now the point I would like to dwell on is this: I have long paid especial attention to phlyctenular ophthalmia because of its frequency in the negro. The negro is often blinded by the disease, a condition that I have never seen in a white patient. I believe that the elevated ring appearing around the cornea and to a certain extent resembling that seen in spring catarrh, is a phlyctenular phenomenon. I have observed every possible transition type and every possible variety of infiltration. The transient nature of the disease, the readiness with which it seems to yield to simple treatment, is notable; the local application of mercury and internal administration of small doses together with keeping the conjunctiva clean suffice to bring about a cure in a very short time. I have never seen the disease last more than three or four months. If you evert the lid and look for changes you find a conjunctiva smooth, natural and not injected. This is not spring catarrh.

Dr. H. Gradle, Chicago—As far as I am aware, this disease had been described only as circumcorneal tumefaction with occasional changes in the conjunctiva of the lids until I called attention in 1884 to the disease limited to the lids without lesion around the cornea. Among some 35 cases seen in Chicago I have found the circumcorneal lesion but twice.

The changes in the conjunctiva are progressive and increase from year to year. During the earlier years they disappear entirely in the winter. Later on both the lesions and the subjective symptoms may not cease entirely during the cold season, although invariably they diminish in severity. I believe I was the first to point out the analogy between spring catarrh and hay fever, both being limited to the warm season and to certain geographical regions. The patient with spring catarrh finds relief as soon as he visits a locality exempt from hay fever. I have seen, however, but one instance of coexistence of spring catarrh and hay fever in the same patient.

May has described the combined occurrence of spring catarrh and trachoma. Personally, I have never seen such a combination. As far as I have seen and learned, a radical distinction between spring catarrh and trachoma is the absolute exemption of the cornea in the former disease. As a rule, too, it is not impossible to distinguish the conjunctival lesions of the two diseases, independently of the history.

In the past two years I have seen at least three instances of conjunctival disease resembling advanced spring catarrh, but without the characteristic periodicity of that disease. These three were all recent affections according to the statements of the patients, but nevertheless they continued with but little abatement after the cold weather had begun. Since close inspection of the conjunctiva excluded trachoma absolutely there has been some doubt in my mind about the diagnosis. These patients, however, were finally cured by the continued use of a suprarenal solution of adrenalin, with the addition of chloretone (0.5 per cent.). In one the lesions and symptoms ceased gradually during the winter. In two others (and perhaps a fourth) the disease subsided gradually during the following warm season on continuing more steadily the same treatment.

DR. WILLIAM ZEUTMAYER, Philadelphia—I desire to corroborate the observations of Dr. Posey regarding the classification of Dr. Burnett. I have long regarded that clinical picture as a racial type of phlyctenular conjunctivitis. To my mind, in vernal catarrh the most characteristic subjective symptom is itching and objective symptom, non-involvement of the fornix conjunctiva.

DR. A. R. BAKER, Cleveland, Ohio—I would like to ask Dr. Posey to detail more fully the diagnostic features of this disease. In my practice I seldom if ever make a diagnosis of vernal catarrh. Either we do not have the disease in Cleveland or else I do not recognize it as such. If you call phlyctenular conjunctivitis "vernal catarrh," of course, we have lots of it, but I have not seen such cases as have been described as occurring in Switzerland and in Vienna.

DR. HIRAM WOODS, Baltimore.—I would like to ask about the pathology of the corneal complications in this disease. In Baltimore we see almost exclusively the variety which Dr. Bruns has described. In two cases under my care there have been corneal complications. It was specially noticeable that while the eyes presented appearances of acute inflammation, there was entire absence of the so-called corneal symptoms, photophobia, lacrymation, etc. Yet there was a peripheral ring of corneal opacity, partly hidden in one case by the swollen conjunctival tissue at the limbus. But for the presence of the acute conjunctival inflammation, one would have thought he was studying a cicatrized annular ulcer. With this absence of corneal symptoms it is improbable that we have acute keratitis. Still, the corneal changes are transient and can hardly be regarded as degenerative.

DR. M. D. STEVENSON, Akron, Ohio—The observation has recently been made that by passing a metallic or glass rod over the conjunctiva itching in the one case or painful sensation in the other would be developed, thus differentiating between vernal catarrh and trachoma. I have sometimes observed the contrary, and consider this statement of little value.

As to the treatment, I would like to mention the use of the *x*-ray. Dr. Smith of Warren, Ohio, has told me of some cases he had treated between the paroxysms of the disease with the *x*-ray with very great benefit. In one case he treated the lid that was most affected, and while its appearance changed but slightly, it did not become inflamed with the beginning of warm weather, while the lid of the other eye did.

Vernal conjunctivitis affects the palpebral conjunctiva chiefly and is often confined to the lids, but seldom to the limbus. True phlyctenulæ in phlyctenular conjunctivitis, on the other hand, are nearly always confined to the conjunctiva of the eyeball. I consider these two diseases entirely distinct and that, although not always easy to differentiate from one another, they are usually quite unlike in course and history.

DR. LOUIS STRICKER, Cincinnati—I would like to endorse what Dr. Bruns has said. I have had much difficulty in making a diagnosis of vernal catarrh, and have restricted the diagnosis to disease of the palpebral conjunctiva, and when I have found it to be a disease of the ocular conjunctiva I have put it down as phlyctenular conjunctivitis, and I treat these cases by internal medication only, with no local applications. I look on it as a peripheral neuritis, a result of toxemia from the intestinal tract. I do not believe there is a vernal catarrh of the ocular conjunctiva.

DR. HAROLD GIFFORD, Omaha—It seems unfortunate that there is a tendency to confound ocular vernal conjunctivitis with phlyctenular conjunctivitis. They are as distinct as they can be. As to its occurrence in the negro, I think Dr. Bruns said he had never seen a case in a negro; is that correct?

DR. BRUNS—Yes.

DR. GIFFORD—I have seen it in a perfectly characteristic form in two negro girls. There was no question of its being phlyctenular conjunctivitis, although the severe forms of phlyctenular conjunctivitis are common in negroes in our vicinity, as Dr. Bruns says.

In regard to the time it occurs, I think we are sometimes mistaken as to its occurring in life, being led to that idea by defective history on the part of the patient. I have seen the trouble crop out after many years of apparent freedom from it in patients I just happened to know had it when 8 to 12 years old. We sometimes see mild forms in children, which fade away, but during a very hot season crop out again, developing perfectly characteristic symptoms.

Another point is in regard to the one-sided cases. I think they are like the one-sided cases of trachoma; cases where they have had it in both eyes and have gotten over it in one. I have followed one such case, where a boy of 5 came to me with vernal catarrh of both eyes. I lost track of him, and after five years he came back with one eye practically normal and in the other a severe form of palpebral vernal conjunctivitis, as severe as I have ever seen. In this case vision was reduced to 20/200 in the affected eye, and, although it would improve under treatment, it would go back with sight greatly reduced, and finally I excised the conjunctiva of the upper lid and replaced it with an epithelial lip-flap. I think that is the only successful operative treatment.

DR. J. H. CLAIBORNE, JR., New York—I think I can array myself on the side of those who have seen vernal catarrh. I have never seen it in the negro, however, although I lived in the south before going to New York. I have seen it in New York City. We find it often in cases of good standing in life rather than in the lower classes, and I know of several cases where it repeats itself every year, and where it is restricted to the ocular and not to the palpebral conjunctiva. I have had the best results with the use of nitrate of silver and atropin and adrenalin combined. I should like very much to see the type Dr. Bruns refers to, and will certainly avail myself of the opportunity if I may.

DR. ROBERT L. RANDOLPH, Baltimore—In regard to the treatment, some five years ago I thought I had discovered what was almost a specific in the use of strong ointment of salicylic acid, but since reporting five cases I have seen two in which it failed. I start with an ointment of 1 per cent. and increase it up to as much as 80 grains to the ounce, or 16 per cent. In the cases of my original report the vegetations were pronounced on the upper lids, and I found with the use of the strong ointment that the vegetations disappeared, leaving a clean conjunctiva. I have since then, however, met with a

case in which the ointment had no effect whatever. It seems to be a trustworthy treatment in the cases of ocular vernal catarrh, but less so in the palpebral form. I have never entertained the idea for a moment that the disease was of bacterial origin.

DR. E. P. MORROW, Canton, Ohio—Dr. Baker spoke of never seeing these cases of vernal catarrh. I have seen a number of cases and am only sixty-three miles south of him. In treatment, the salicylic acid ointment, just spoken of by Dr. Randolph, has given me the best results. The strength I have used has been from 5 to 10 grains to the ounce. The intense itching complained of by these patients is entirely relieved by the application of ice cloths, the method of applying them being the same as employed in purulent conjunctivitis. I believe that this tends also to shorten the disease.

DR. WM. CAMPBELL POSEY, Philadelphia—As to the occurrence of the disease in different parts of the United States: Men who have lived in Maine many years have told me that they had never seen a case there, and I have had an opportunity of personally observing that one case at least who presented very marked symptoms in Philadelphia was immediately benefited by a change of residence to Mt. Desert Island.

It is only in the cases where there are the hard, rounded granulations on the lids that the diagnosis is difficult, and in those the absence of pannus and the history will generally suffice to differentiate them from trachoma. I have observed a number of cases of vernal conjunctivitis in negroes, both of the palpebral and ocular forms, but I believe that most of the cases referred to by Burnett are of phlyctenular origin. In conclusion, I would like to call attention to the employment of the *x*-rays in the treatment of vernal conjunctivitis, especially since I have just received a letter from Dr. Bennett of Buffalo, in which he states he has had most excellent results in one case from this method.

Clinical Report.

A CONGENITAL SACRAL TUMOR.

RICHARD T. HENDERSON, M.D.
URBANA, OHIO.

History.—I was called, April 10, 1903, to see Mrs. L., a medium-sized woman, apparently healthy, aged 30. She was the mother of two children, the younger being 2 years old; she had never had any sickness since the diseases of childhood. Her family history was good. She was at about the seventh month of gestation.

Examination.—Her excessive abdominal enlargement was double that of any woman I had ever seen at full term. Palpation was impossible, as the slightest pressure caused excruciating pain. She was unable to assume the recumbent position owing to dyspnea.

Labor.—After being called once by a false alarm, I found her in labor April 20, the contractions being short and of not much force, though she said she had been in labor for five hours. Dilatation had taken place to the size of a silver dollar. Three hours later there was more dilatation. The contractions, however, seemed to be on the wane, though the woman was not in the least exhausted. After twelve hours of labor, the contractions becoming weaker and weaker and the intermissions more and more prolonged, I ruptured the membranes. A flood of water, at least five pints, passed at once. With a few strong contractions the head was now born, with the cord wrapped around the babe's neck. There everything stopped. After loosening the cord (in which I found no pulsation) I waited one-half hour for a return of contractions, but as none occurred, I began gentle traction. This caused such agony that I was forced to desist. I anesthetized her completely and easily delivered the shoulders, but was unable to accomplish anything further. I introduced my hand and found what I took to be the buttocks of another child, but was soon surprised to find this mass firmly attached to the buttocks of the half-born babe. I then drew down both feet and began traction. After fully thirty minutes' traction the tumor was delivered, followed by a quart of water. The third stage was normal.

The tumor was located on the sacrum and coccyx, and was 18½ inches in circumference.

The woman rallied slowly, then did very well for six days. On the sixth day she had a chill and a temperature of 106.

After treatment by the administration of quinin and by vaginal and intrauterine irrigation the temperature returned to normal and the patient recovered her usual health.

The County Society the Unit.—A year's work under its new constitution and by-laws has shown where certain changes are imperatively necessary to the proper and successful carrying out of the society's work in harmony with the American Medical Association. The existence of "members at large" is in conflict with the spirit, if not, indeed, with the law of the A. M. A., and all such "members at large" should be obliged to join their county societies. It is the county society that is the fundamental unit of organization—properly so—and all licensed and reputable physicians should belong to this fundamental organization. Anything other than this would be as inconsistent as permitting a man becoming a member of the Knights Templars without being a member of a "blue lodge." The illustration cited is further apropos, for the whole plan of reorganization of the A. M. A. is merely an adoption of the general fraternal society plan. Therefore, we would say to all members at large, "Join your county society, or the county society nearest to your home, if there is none in your own county."—*California State Jour. of Med.*

SATURDAY, JULY 25, 1903.

THE ETIOLOGY OF SYPHILIS.

It requires but the briefest survey of the literature of syphilis to realize the stupendous amount of work that has been done for half a century in searching for a microbic cause of the disease. It seems as if most of the individuals who have begun the search succeeded in finding a microbe, and under the force of enthusiasm, rather than of satisfactory proof, many have claimed the rôle of specific etiology for their organism.

The name of Donné is one of the first, if not the first, to be associated with the microbic etiology of syphilis, but this was more or less unintentional on his part, apparently, as his partisans state that he did not believe certain organisms he found in the discharges of syphilitics were the cause of the disease. His work was published in 1837. No noteworthy contribution to the subject was made until 1869, when Hallin claimed that a micrococcus which he found constantly in the blood of syphilitics caused the disease. This was a queer organism. It was found in the red blood cells, which became enlarged and vacuolated as a consequence of the invasion, and after a time they acquired ciliary elongations. It will be remembered that a few years ago Arnold described a number of morphologic peculiarities which develop in red blood cells as a result of standing. Hallin's observations in syphilis probably concerned some such artefact. In the same year Klotzsch found certain "spores" in the blood and skin lesions and cultivated them in broth; but his cultures were not taken in the light of confirmatory evidence by his contemporaries.

The "crypta syphilitica" of Salisbury and Brühlkens, which was published in 1870, was followed shortly by two discoveries of meteor-like career. Klebs, in 1870, described a remarkable organism, cultivated from syphilitic lesions, which was capable of growing either as a coccus or a bacillus, and often in peculiar and characteristic masses. It would seem probable that he had a mixed culture. However, he succeeded, to his satisfaction, in conveying syphilis to monkeys by inoculating this culture. He also infected monkeys with syphilis by direct transplantation of chancres. Then Lostorfer held the attention of medical scientists for some months with his "corpuscles of syphilis." They were seen to develop in syphilitic blood which had been kept for a few days in a moist chamber. There seems to have been an interesting sitting of the Wiener Medicinische Gesellschaft at this time, when Lostorfer volunteered to base the diagnosis of syphilis on an examination of the blood. The opportunity was given him, and he is said to have arrived at the differential diagnosis with considerable exactness in this way. But soon other observers found the same "corpuscles" in the blood in health and in various diseases, and the conclusion was reached that they were disintegration products, "granules of paraglobulin," as one writer said.

There appear to have been some equally successful observers in America at this time. Bermann of Baltimore had found bacilli and micrococci similar to those of Klebs, in the sections of the tissues, particularly in the vessels. Some critics believed he was studying intravascular fibrin. Then there was the dramatic demonstration of the fungus of syphilis by Cutter of Boston at a meeting of the American Medical Association held in Chicago in 1878. He found mycelium in the chancres by the use of a 1/50th and a 1/75th objective lens.

In 1881 Aufrecht found a micrococcus or a diplococcus in papular lesions, and Obraszow a similar organism in lymph glands. The findings of Birch-Hirschfeld, also of Peschel, in 1882, differed little from some previous observations. They found groups of cocci in all gummatous tumors except those which were cicatricial, in mucous patches, papules, and in indurated chancre. The best results were obtained by a study of fresh tissues in either acetic acid or potassium hydrate. Those who have used these solutions in the study of fresh tissues will recognize how closely various granules may simulate cocci. In the same year the results of Martineau were published. He introduced hogs into the experimental study of syphilis, claiming to have transferred the disease to them by inoculating cultures of hard chancres. These cultures were made by placing the chancre in a liquid medium at brood-oven temperature, a growth of micrococci resulting. The overlying liquid was used in the inoculations. The hogs underwent a papular eruption and the microbes could again be cultivated from the blood; they resembled somewhat those described by Klebs. He also gave monkeys a hard chancre on the prepuce which was followed in time by a characteristic papular eruption. Many others since then have obtained micrococci from syphilitic lesions, but there were also published valuable negative results, especially by Köbner (1883) and Neumann (1883), who failed utterly in the attempt to inoculate animals with syphilis.

Of all the micro-organisms observed or described in syphilis the bacillus of Lustgarten (1884) has been accorded the most favorable reception up to the present time. It will be remembered that this organism resembles the tubercle bacillus in morphology and staining properties, but is more easily decolorized by acids. He found it in small numbers in the primary sores and in internal organs in all of sixteen cases examined. It has never been cultivated artificially. Confirmatory work on this organism was undertaken by several observers. De Michele and Radice found it in forty-five out of sixty-four cases examined. It seems that Doutrelepont

and Schutz had carried on studies contemporaneously with Lustgarten and shortly after the latter's report described an organism resembling or identical with the Lustgarten bacillus (1885). It was found in two initial scleroses, two broad condylomata, a papule from the chin and a gumma. It occurred singly or in small groups especially at the periphery of lesions, but often many sections contained no organisms.

De Giacomi and also Gottstein (1885) were able to demonstrate the Lustgarten bacillus in a number of cases in both initial scleroses and gummata, and offered some improvements in the staining methods. Many others have been unable to find the organism, notably Sabouraud (1892), who after a study of twenty cases concluded Lustgarten had found only a pretty stain for the tubercle bacillus. This may not have been entirely just to Lustgarten.

More recently interest in the etiology of syphilis has revived. V. Niessen since 1898 has been publishing assiduously descriptions of his organism and his animal inoculations. As this is a pleomorphous organism, usually a streptobacillus, he is willing to concede that Klebs, Lustgarten and others may have seen one or another of its forms. It stains by Gram's method, is easily decolorized by acids, has endospores, and is found in all lesions and in the blood in all stages of syphilis, and it is supposed under no other conditions. He has been able to cultivate it, to produce syphilis in rabbits by injecting the culture, even to the extent of causing hereditary syphilis (abortion). The bacillus was found in the fetal lungs, and a papular eruption and ulcerated buttocks were present! Since the organism was present in all stages of the disease he concluded that syphilis is absolutely incurable. V. Niessen has met a great deal of ridicule among the Germans.

In 1901 de Lille and Julien cultivated a Gram-staining bacillus from the blood which was pathogenic for guinea-pigs and frogs and was agglutinated by the serum of syphilitics. The hog has been used for inoculation with syphilitic blood and excretions especially by Adrian and by Hügel and Holzhauser, and they claimed to have caused a generalized papular eruption which appeared about four weeks after the inoculation.

Joseph and Piorkowski have attacked the subject in a novel way. Since it seems probable that the sperm of syphilitics may infect a woman and convey syphilis to offspring, they concluded to study the sperm bacteriologically. They thought also that placental tissue might logically be a good culture medium. This was accordingly inoculated with the sperm of syphilitics and with that of healthy men as controls. Subtracting everything that was considered contamination, they centered their attention on certain clear colonies made up of a motile bacillus having the morphology of the diphtheria bacillus and the size of the subtilis bacillus. It stains by Gram's method, is not acid-proof and degenerates soon, with the formation of metachromatic granules. It has since been cultivated on various ordinary media. The positive findings occurred in about forty cases in stages varying from five weeks to five years of the disease, and was absent in the sperm of fifteen normal cases; positive results were secured also in twenty-seven hard chancres, in papules, mucous patches and other lesions. No satisfactory animal experiments have been obtained.

The medical profession appeared to have been little impressed with the protozoic cause which Max Schüller discovered about two years ago. He incubated syphilitic tissue and found the development of bodies resembling protozoa, which some German critics considered cork cells. The fact that he found similar "organisms" in carcinoma and sarcoma added no strength to his theory.

We may say that now we are confronted with the bacillary theory of syphilis, in contradistinction to the micrococcus theory which prevailed in previous years. It appears probable that several recent observers have been studying the same bacillus, particularly would this seem true in regard to the Gram-staining organism. And one may say that circumstantial evidence against this form of organism is accumulating rather formidably. But unfortunately confidence is often lessened in the work published because of hasty conclusions on the part of the investigators. A papular eruption in a hog or rabbit is surely not easy of recognition, and it is possible that many organisms may be able to produce it. And there are perhaps many organisms which would cause a rabbit to abort, as any infectious disease might; and excoriations on the buttocks of an immature, thin-skinned, fetal rabbit may have many explanations. Moreover, it does not follow that the specific germ for syphilis would be pathogenic for animals in the same way as in man. In pathology there are many instances where this is illustrated. Then the agglutination test for specificity of an organism can not be relied on unless it is most carefully controlled by experiments with normal serum.

In this day of rapid scientific progression, it is not to be forgotten that with new methods of differentiation, new burdens of proof have to be met.

INFANTILE HYPERTROPHIC STENOSIS OF THE PYLORUS.

The increasing number of reports of this disease, the contentions over its surgical or medical treatment and opposing views as to its nature and cause, it is to be hoped, will soon lead to a few careful and thorough anatomic studies. The earlier conception of its fundamental congenital genesis, at least for the majority of cases, has been abandoned; this is mainly due to the absence of symptoms for varying periods after birth. In the 23 cases collected by Pritchard in 1900 there were some in which symptoms were not observed until the infants were several months old. The absence of any reports of increased connective tissue in the histologic studies of the hypertrophied pylorus is also to some extent opposed to the intrauterine development of the condition. In a small number of cases, a prenatal stenosis at the pylorus may occur, as it does in other parts of the

alimentary canal, e. g., imperforate anus or ileocecal valve.

There are reasons for believing that the name of the affection might with advantage undergo further modification—the designation congenital having been dropped—since it is altogether likely that the obstruction of the pylorus is but one phase of a series of events and does not primarily cause either the repeated emesis or the final death. Numerous instances of stenosis of the pylorus are recorded in adults; the observation by Landerer of a stenosis, the passage way measuring only 2 mm., in a man who lived to the age of 45, is a notable example. In a number of the cases reported of stenosis in infants, the obstruction was not as marked.

There are certain difficulties confronting investigation of the infantile hypertrophic stenosis; for instance, there is at present no means of determining whether, at the time of fixation of the specimen, unstriped muscle fibers are in a condition of contraction or relaxation; in consequence, those who maintain that the obstruction of the pyloric orifice is caused by tonic spasm are unable to find in the microscopic examination anything to refute or confirm such an idea. Accurate measurements of the infantile pylorus, its caliber, and the thickness of various coats, at different periods of development, are also wanting.

The anatomic change in the specimens examined is a remarkable hypertrophy of the layer of circular fibers. Whether this hypertrophy is only apparent and caused by "systole," as is urged by Pfaundler and others, or whether it is real and secondary to prolonged contractions, remains to be determined. In some instances the stenosis has disappeared with the pressure of a column of water of a certain height, implying thereby a condition unassociated with organic disease.

One direction research should take is the careful examination of the nervous system of these infants, for it is to be remembered that Yzeren was able to produce forcible and prolonged contraction of the pylorus and adjacent region in dogs and rabbits by section of the vagi. That alterations in the innervation of the stomach may be responsible for this disease of nurslings has occurred to more than one observer; examination of the nervous system, so far as we know, has not been made. Degenerative changes in the vagi, or their nuclei of origin, and consequent lessening of their inhibitory action, might result in spasm to which hypertrophy was secondary.

The number of reported cases is now over 50; two or three years ago it was half that number; of the 50, 20 have been operated on, with eight deaths. Pylorectomy, pyloroplasty, dilatation of the pylorus (Loreta's operation) and gastroenterostomy have all been performed, the last two with greatest frequency. The difficulty and high mortality attending and following surgical intervention are discouraging, and, on the other hand, good results are reported from attention to the diet. The presence of free HCl in the gastric juice, as determined by Knöpfelmacher and in a number of cases recently by Freund,[1] with their recommendation that cow's milk, raw or skimmed, be given to counteract this, also point to the eventual removal of the affection from the domain of surgery.

SUICIDES OF PHYSICIANS AND THE REASONS.

Incited by a cable dispatch from London announcing a great increase of suicides among physicians in Great Britain, the Chicago *Tribune* reviews the records for the United States, and finds for the past twelve and one-half years that a total of 519 physicians have committed self-murder. The average annual number is about 41, which has been exceeded six times in twelve years. The smallest number was 23, in 1891, while the largest number was 53, in 1893, a time, by the way, of great financial depression. A record for the first six months of 1903 indicates that the present year will probably be up to the average. The above figures, while not indicating such an increase as is reported from abroad, are sufficiently formidable as they are; they far exceed the average ratio of suicides in the general population, in this country at least, and are suggestive in many ways. In Great Britain the cause of the increase is attributed largely to depreciation of income. They suffer there from overcrowding of the profession, competition with quacks and the exploitation of the medical profession by workingmen's clubs, which has become a standing theme in our English contemporaries. In this country we have the trouble of overcrowding to even a greater extent, for here we have twice the number of physicians in proportion to the population as in Great Britain. Moreover, the world is getting healthier, and this healthfulness, again, is largely due to the labors of physicians, who are the only ones that work against their own interests continuously. Mainly through their efforts morbidity is greatly decreased and the professional income of the physician is also diminished.

We have here, moreover, greater competition with quacks and all aberrant sects, like Eddyism, Dowieism and others than do our confrères abroad, and we are annually educating, as Dr. Billings has shown, about twice the number that is required to fill the naturally occurring vacancies in the profession. It is not remarkable, in considering these facts, that failures must occur, that many of our professional brethren have to drop out of the profession in one way or another, and that weaklings, those morbidly disposed, and those lacking in high principles and moral inhibitions, might very easily adopt suicide as the most direct way to end their troubles. That more do not do this we think speaks well for the profession, both here and elsewhere.

Another reason suggested is that the physician is familiar with death in all its forms, and always has the means of suicide at hand. This is also probably worthy of consideration in connection with the materialistic tendencies which, we think, exist too much among us.

1. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1903, xi, 309.

It is not a bad thing to be reminded of unpleasant facts, if by such reminders any influence whatever is exerted toward doing away with the evils that exist. If we know that physicians are disproportionately given to suicide under the stress of modern life, while other professions also suffering from overcrowding are not, it is well to look for the reasons. The real main factor is, we believe, the business negligence of the profession as a whole. It does not look out for its own interests as it might very properly do without in the least disregarding the interests of the public. With proper organization and regulation, which is now, we believe, fairly well inaugurated, though far from being perfected, there will be less reason, we trust, in the future than there has been in the past for suicide among physicians.

THE STRIKE FEVER.

An Indiana official has, according to newspaper reports, diagnosed the cause of the present epidemic of strikes as due to a bacillus. As far as its prevalence and apparent contagion goes, it would seem to be a rational conclusion that there is some sort of morbid virus or germ extant that produces the present outrageous condition of things. The extirpation of this particular germ, however, is a sociologic problem, not a medical one, except in so far as the mental condition of the strikers at the present time is a psychologic phenomenon that deserves some attention by the psychiatrist. There is no question, however, that if the present febrile movement continues there will be some complications calling for medical treatment. The enforced idleness of a large number of working people and their consequent financial embarrassment, will have much to do in depreciating their bodily welfare, and in causing impairment of natural immunity. Should the "epidemic" go further, the public at large will suffer. Great sociologic injury may easily result from extensive stagnation of manufacturing and other occupations, and the financial condition of the country may thus be seriously interfered with. These results are an interesting matter for study, both in their influence on present pathologic conditions of the laboring classes and on the people as a whole.

THE YELLOW FEVER ORGANISM.

Within the past two or three years the number of the animal parasites known or suspected to be the cause of disease has been notably increased, and if the extension of our knowledge in this direction continues at the same rate, we may have to modify our terminology to some extent, and instead of the name "bacteriology" as a branch of medical science, use some more comprehensive term. One of the latest additions to the list is the *Myxococcidium stegomyiæ,* which Drs. Parker, Beyer and Pothier[1] of the Public Health and Marine-Hospital Service find as a regular denizen of the yellow fever contaminated mosquito. It is true that not all the steps necessary to positively assure us of the etiologic importance of this organism in yellow fever have yet been taken, or at least, if taken, have not been published, but it has a respectable—if that be the word—standing on the suspected list. We can hope at least that it will be determinately ascertained to be the cause of this tropical scourge, and that by the further study of all its life history we can in time exact a still more efficient control over the disorder. It is something to know, or even reasonably suspect, who are our enemies, and be able to act accordingly. The authors make no claim to the discovery of the genuine organism, though they evidently are not unwilling to call attention to the fact that their discovery strongly points that way. There is an apparent advantage in the study of these pathogenic animal organisms over that of bacteria; we have in them a fuller life history to work out, and while specific characters are not as marked as in the higher organisms, there are more to characterize them in a biologic point of view than is the case with the lowlier vegetable forms. The field, however, is wide enough in both, and either may have its special advantages in the study of its life cycles and that of its toxic action and constituents.

1. Report of Working Party No. 1, Yellow Fever Institute, Public Health and Marine-Hospital Service, Washington, 1903.

RESEARCHES ON DENGUE.

In connection with the above we may say here that the catalogue of the iniquities of the mosquito is not yet exhausted. Besides its maleficent function as the transmitter of malaria and yellow fever and its general character as a pestilent nuisance, there is yet another disease of tropical and warmer temperate regions that is being credited to its mischief. The Hawaiian Board of Health has already taken action against it as a factor in the spread of dengue, and in the *Journal of Tropical Medicine,* July 1, Dr. H. Graham of Beyrouth, Syria, reports his investigations into the causation of this disease, and his conclusion derived therefrom that it is due to a protozoön conveyed and inoculated by the mosquito. He has found and studied the evolution of a parasite in the mosquito and in the blood of dengue cases that seems to him satisfactorily assured as the cause of the disease. Dengue not being a fatal or serious disorder, he found no difficulty in obtaining plenty of human subjects on whom to experiment; indeed, he says the difficulty was to select the best from the multitude who offered for the sake of the compensation paid. His experiments paralleled to some extent those of Reed and his associates with yellow fever, and though they were not so elaborate and conclusive, yet they seem, as related, to afford a very fair presumption in favor of his conclusion. The species of mosquito chiefly implicated appears to be *Culex fatigans,* but the notorious *Stegomyia fasciata,* which coexisted with it in Beyrouth and its environs where the experiments were made, is perhaps not above suspicion. The culex, however, seems pretty well convicted of being a harborer of the germ. Experiments were also made with inoculation of the salivary glands of this species, carefully dissected out and mixed with a warm sterilized normal peptonized saline solution. These inoculations produced an attack in every way similar to dengue, but so severe that he desisted from further experiments in this line. It would seem that in this way a particular concentration of the virus was obtained. Dengue organisms were found in the blood of the patient, thus removing the suspicion of septicemia in

the case. If Graham's findings are confirmed in other parts of the world where dengue abounds, and the special variety or varieties of mosquitoes accurately determined, it will be another victory for preventive medicine over a most annoying, if not actually dangerous, affection.

Medical News.

ILLINOIS.

Personal.—Dr. Herman A. White, St. Charles, will sail for Europe August 4.

State Officials Enjoined.—Joseph Hanreddy, the lowest and an unsuccessful bidder for the contract to erect eight cottages at the Illinois Hospital for the Incurable Insane, at Bartonville, has filed a bill asking an injunction against the state auditor, the trustees of the hospital and the contractor, alleging fraud in the awarding of the contract.

Chicago.

Vaccination and Smallpox.—Of the 311 cases of smallpox which have come under observation and treatment in Chicago this year, only 39 showed any evidence of vaccination whatever, and not one of these had a recent, protective vaccinal mark; they were all adults who either showed marks of vaccination in childhood, never revaccinated, or doubtful, non-characteristic scars, as of burns or other injuries.

Personal.—Dr. N. Senn is taking his vacation in the west. He went by way of Rock Springs, Wyo., where he was the guest of Dr. R. Harvey Reed, to the Yellowstone Park, and from there will visit the Yosemite Valley.——Dr. Julius Grinker has returned from Europe.——Dr. George W. Newton and family sailed for Europe July 18.——Dr. Stanton A. Friedberg sailed for Europe July 17.——Dr. and Mrs. William Cuthbertson have returned from their European tour.

Less Contagious Disease.—Only 57 cases of the contagious diseases—diphtheria, measles, scarlet fever, smallpox, etc.—were reported during the week ended July 18. This is the lowest number since September, 1901. In the corresponding week last year there were 119, and the 34 cases of diphtheria and 14 cases of scarlet fever reported this week are one-third and one-half less than the respective number reported during the previous week. Measles, which has been epidemically prevalent for many months, is fast disappearing, as also is smallpox, the solitary reported case of which was that of an unvaccinated infaut of 6 months.

Comparative Mortality.—During the first six months of 1903 a total of 15,201 deaths from all causes were reported, giving an annual death rate of 16.24 per 1,000. This is an increase of 3,103 deaths over the number for the first six months of 1902, and an increase of 18.5 per cent. in the annual rate in proportion to population. Of the causes of death showing the greatest rate of increase were typhoid fever, 154 per cent.; scarlet fever, 147 per cent.; measles, 136 per cent.; pneumonia, 60 per cent.; Bright's disease, 58 per cent.; acute intestinal diseases, 29 per cent.; suicide, 24 per cent.; consumption, 17 per cent.; heart diseases, 14 per cent. Pneumonia caused 3,133 deaths in these six months, as against 1,961 in the first six months of last year, and consumption 1,561 and 1,325 respectively.

MARYLAND.

Baltimore.

Doctors Indicted.—Drs. Robert X. Giering and Anna Giering were indicted by the grand jury, July 15, on the charge of publishing improper matter in a medical book. The former gave $300 bail; the latter is said to be out of the city.

Deaths of Last Week.—There were 124 deaths of children under 5 last week. This was nearly one-half the entire mortality, which was 251, equivalent to an annual rate of 23.41 per 1,000. There were 60 deaths from cholera infantum, and 4 each from typhoid fever and sunstroke. Consumption and pneumonia caused respectively 19 and 12 deaths.

Faculty Changes.—The following changes have been made in the faculty of the Maryland Medical College: Dr. George B. Scholl, associate professor of pathology and bacteriology; Dr. Gustavus Dohme, demonstrator of chemistry; Dr. Clarence P. Erkenbrack, lecturer on osteology, and Dr. Wilbur M. Pearce, clinical professor of diseases of children and physical diagnosis.

Personal.—Dr. Eugene F. Cordell has resigned the chair of practice in the Woman's Medical College and has accepted the honorary professorship of history of medicine in the University of Maryland.——Dr. N. G. Keirle, Jr., has resigned his position as resident physician of the Hebrew Hospital and will go abroad in August to study the Pasteur treatment.——Drs. Ridgely B. Warfield, Harry Friedenwald and Thomas R. Brown have gone to Europe.——Dr. Hunter Robb sailed for Antwerp, July 18.——Dr. Joseph E. Evans, Merion, S. C., has been appointed to the Marine-Hospital Service and assigned to duty at the Marine Hospital here.——Dr. Alfred H. Powell is again resident physician at Capon Springs, Va.

MASSACHUSETTS.

Goat's Milk for Babes.—There has been started in Malden, Mass., a goat farm for the production of goat's milk. The promoters expect that there will be a large demand for the milk, especially for the dietary treatment of sick babies.

Largest Class on Record.—More than 200 applicants took the examination before the State Board of Registration in Medicine, in Boston, July 14. Never before has so large a number appeared to take the examination for license to practice.

Personal.—Dr. Edward O. Tabor has been elected city physician of Lowell.——Drs. Ralph H. Seelye and Charles P. Hooker have resigned from the staff of Mercy Hospital, Springfield; Dr Charles J. Downey has been made visiting physician, and Dr. Harvey W. Van Allen electro-therapeutist to the hospital.

Free Antitoxin and Vaccine.—The law having been enacted which makes it the duty of the State Board of Health to manufacture for free distribution both diphtheria antitoxin and vaccine virus, the state bacteriologist, Dr. Theobald Smith, who will have charge of their production at the Bussey Institute, has gone to Europe to study the best methods of production there, specially in Germany.

Boston Deaths.—The report of the Boston Board of Health for the year ended Jan. 31, 1903, shows the lowest death rate ever recorded, 18.73 per 1,000, or .97 lower than the year before. The large items in this decrease were in zymotic disases, 360; in diphtheria, 128; in scarlet fever, 123. Typhoid fever caused 139 deaths. Of children under five there were 3,367 deaths, a decrease of 102. The total number of deaths for the year was 10,983.

Mortality of the Week.—With the coming of the hot weather the city's death rate, which was phenomenally lower in June, has returned to more usual conditions, and for the week ended July 18 was 18.58 per 1,000. Of infectious diseases 31 cases of diphtheria were reported, with 5 deaths; 20 of scarlet fever, with 3 deaths; 16 of typhoid fever; 23 of measles, and 34 of tuberculosis with 18 deaths. Pneumonia caused 25 deaths, and heart disease 21. The number of babies under one year who died was 52, and of children under five years, 67.

Brookline's Fight Against Mosquitoes.—Brookline's efforts to exterminate mosquitoes, which seemed so successful early in the season, have met much criticism and ridicule more recently, when the wet weather, followed by humid heat, has produced a scourge of the pests everywhere. The difficulty seems to be that a large sum of money is needed to do thorough work, and that is not available to the board of health. Steady work is being done, however, both in filling in, drainage and petrolizing. An attempt may be made to enforce the town ordinance which makes a pool of stagnant water wherever found a public nuisance.

MICHIGAN.

Pitcher Acquitted.—Dr. Sheldon Pitcher, Detroit, charged with causing the death of a young woman by a criminal operation in September last, was acquitted, June 18, by a Recorder's Court jury.

Refuse to Register.—The State Board of Medical Registration has declined to register Dr. D. M. Cooley, who attained some unenviable notoriety while a student at the Michigan College of Medicine, Detroit, by alleged unethical practices, and who obtained a diploma only on his signing an agreement to go out of the patent-medicine business.

Personal.—Dr. Elliott K. Herdman, Ann Arbor, has been appointed medical inspector of schools.——Dr. Oscar L. Dales has been appointed a member of the board of health of Grand Rapids, vice Dr. Hugh Lupinski, deceased.——Drs. John H. Neary, John W. Hoffman, William S. Brownell, Moses A. Fechheimer, George W. Augustin and William P. Melody have been appointed city physicians at Detroit.

Comparative Morbidity.—For June compared with the average for June in the 10 years, 1893-1902, nephritis, scarlet fever, typhoid fever, smallpox and diphtheria were more than usually

prevalent; and neuralgia, diarrhea, consumption, pleuritis, intermittent fever, remittent fever, inflammation of bowels, erysipelas, whooping cough, cholera morbus, cholera infantum, meningitis and dysentery were less than usually prevalent.

The Most Dangerous Communicable Diseases.—Meningitis was reported present during June at 3 places; whooping cough at 43 places; typhoid fever at 65 places; diphtheria at 68 places; smallpox at 107 places; scarlet fever at 109 places; measles at 113 places; and consumption at 208 places. Meningitis was reported present at 3 places less; whooping cough and typhoid fever at the same number of places; diphtheria at 9 places more; smallpox at 20 places less; scarlet fever at 22 places less; measles at 22 places less, and consumption at 12 places more, in June, than in the preceding month.

June Mortality of Michigan.—There were 2,319 deaths reported in June, corresponding to an annual death rate of 11.4 per 1,000. The number of deaths was 414 less than the previous month. There were 378 deaths of infants under 1 year, 149 deaths of children aged 1 to 4 years and 699 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 200; typhoid fever, 22; diphtheria, 56; scarlet fever, 10; measles, 19; whooping cough, 28; pneumonia, 128; diarrhea and enteritis, under 2 years, 65; cancer, 133; accidents and violence, 164, including 23 from drowning and 2 from lightning. There was a general diminution in the mortality from the causes given, as compared with the preceding month. Five deaths were reported from smallpox, and one death from chicken-pox.

NEW YORK.

Buffalo Personals.—Dr. William H. Callahan has been appointed health officer of Chautauqua for the season.——Dr. Roswell Park has suffered a relapse from erysipelas, but is again improving.——Dr. Marcello Hartwig is still confined to his home.——Dr. Charles Cary has returned from abroad.——Dr. Joseph W. Grosvenor has been elected president of the Buffalo Academy of Medicine.

Thousands Wanted for Consumptives.—The commissioner of charities of New York city has submitted a report on the question of establishing a municipal sanitarium for consumptives at some out-of-town but accessible locality. He recommends an appropriation of $400,000 to enable the health department and the board of trustees of Bellevue and allied hospitals to proceed with the work.

June Deaths in Buffalo.—The monthly report of the department of health shows an annual death rate of 1,282 per 1,000. The principal causes of death were as follows: Consumption, 44; cerebrospinal meningitis, 4; diphtheria, 7; typhoid fever, 9; debility, 34; cancer, 35; apoplexy, 13; meningitis, 13; valvular heart disease, 24; appendicitis, 5; nephritis, 15; abortion, 1, and violence, 29. The total deaths were 406, as compared to 364 for June, 1902. The small number of deaths from typhoid fever, in view of the typhoid fever agitation for purer water, is noteworthy.

Warns Against Second Epidemic in Ithaca.—Dr. George A. Soper, New York, who was sent to Ithaca by the State Department of Health to have charge of the sanitary measures during the typhoid epidemic, has reported to the board of health that there is great danger of another epidemic resulting from the use of infected water. There are now no less than 9 persons ill with the fever, with 5 suspected cases. He had just discovered that in a residence situated near Six-Mile Creek, a man has been ill with the fever for ten days, and that in all probability the refuse germs had washed directly into the supply from which the most of the citizens get their water. The city is practically in the same danger of an epidemic as it was in February and March.

PENNSYLVANIA.

New Hospital Opened.—The new Frankford Hospital fills a great need in one of the greatest manufacturing districts of Philadelphia. Equipment of the hospital is being rapidly accomplished through the generosity of its president, Dr. J. Bruce Burns and others.

Smallpox Situation in Hand.—The new smallpox cases for the week ended July 18 numbered 24, as compared with 54 for the previous week. The health officials will not relax their activity in fighting the disease, but will continue vigorously the campaign of vaccination and other preventive measures. They have confidence that they are getting control of the situation.

Condensed Tuberculosis.—Dr. Lawrence Flick, manager of the Phipps Institute for the Prevention and Cure of Tuberculosis, is said to have determined that a comparatively small area, that east of Broad street and south of Market street, has more cases of tuberculosis than all the rest of Philadelphia. This district is teeming with foreigners, especially Italians and Russian Jews, often crowded into the filthiest tenement houses, with meager fare and less pure air.

Hospital Roof Garden.—On July 14 the new roof garden of the Philadelphia Hospital was formally opened. This roof-garden, providing the open-air life for the consumptive male inmates, was built under the direction of Director Martin. It is 30 by 200 feet, and covered with canvas, giving the appearance of a huge tent. Cots are provided for about 100 patients. Flowers and plants brighten the place. An elevator runs from the first floor to the roof. The plan is somewhat of an experiment, and a careful study of the effect of this mode of life on the consumptives is to be made.

To Prevent Tetanus.—For the week ended July 18 at least three more were added to the list of deaths from tetanus in Philadelphia, making 9 since July 4. Many deaths from the same cause are reported from Pittsburg, Reading, Harrisburg, Wilkesbarre and various points throughout the state. It is believed that the district attorney of Philadelphia will prosecute dealers who illegally sold pistols to children. The State Board of Health has instructed its committee on poisons and explosives to recommend the passage by the legislature of an act to prevent the use of toy pistols by minors.

Hospital To Be Reconstructed.—The contract has been let for $150,000 for the reconstruction of the Medico-Chirurgical College Hospital, Philadelphia. When the work is completed the building will be practically fire-proof, and the equipment will be entirely modern. The work of the hospital, now chiefly confined to emergency cases, is temporarily transferred to a series of houses nearby, owned by the institution. The college, by the will of the late Dr. Spencer Morris, formerly professor of medical jurisprudence and toxicology, bequeathed $12,250, the income of which is to be awarded annually to the member of the graduating class who received the highest general average for the degree of doctor of medicine.

Boards of Health Meet.—On July 16 the State Board of Health, with representatives of similar boards of other states, met at Marietta, Pa. Reports of inspection of the Schuylkill River were read, and some of the sources of pollution pronounced abated. Secretary Lee was instructed to file a petition with the Court of Common Pleas of Montgomery County asking for an injunction to restrain the borough of Norristown from discharging its sewage into the Schuylkill. The number of cases of smallpox for May and June in the state was 1,092, with 62 deaths, as against 1,416 cases and 61 deaths for the preceding two months. The conditions in rural districts where epidemics had prevailed were reported as much improved. Dr. Samuel T. Davis of Lancaster was re-elected president, and all the old appointees of the board were retained.

GENERAL.

Scourge of Mosquitoes in New England.—Because of the wetness of the season, there is an enormous increase of mosquitoes along the North Atlantic coast.

The Mosquito Further Indicted in Honolulu.—The Hawaiian Board of Health has decided that the mosquito is the cause or an agent in the spread of dengue which has prevailed in the territory for some months, over 1,500 cases having occurred, and will take measures for the extermination of the insects.

The Government Borax Diet Tests.—It is announced that the official report on the tests of preservatives in food, which have been carried on in the Department of Agriculture, will be ready July 29. Only borax has been administered in the food thus far. Experimentation has been suspended for the summer, and will be resumed October 1. The health of several of the men who were fed on the preserved food is said to have suffered so as to compel their withdrawal from the tests.

Yellow Fever Commission Reports.—The U. S. Commission appointed to investigate the transmission of yellow fever has reported, after six months' study, as follows:

1. That the bacteriologic examination of the blood of cases of yellow fever during life and the blood and organs at autopsy performed immediately after death in uncomplicated cases is negative.
2. That stegomyia fasciata when contaminated by feeding on a case of yellow fever forty-one and a half hours after the onset of the disease and subsequently fed on sugar and water for twenty-two days, one and a half hours, can, when permitted to feed on a non-immune individual, produce a severe attack of the disease.
3. That stegomyia fasciata, contaminated by yellow fever and after varying periods killed, sectioned and appropriately stained, presents with regularity a protozoan parasite, myxococcidium

stegomyiæ, that can be traced through a cycle of development from the gamaete to the sporozoite.

4. That stegomyia fasciata fed on blood from a case of malarial fever on normal blood or artificially fed does not harbor the parasite indicated in conclusion three.

Manila Medical Society.—A circular letter issued by this society calls attention to the fact that while it has been in existence only a little over a year; it now has a membership of nearly forty, including American, English and native physicians. The circular letter, sent to members of the profession in Manila who are not already members of the society, calls attention to the fact that it is "a field rich in opportunities from a scientific standpoint, and it is our duty to ourselves, to our colleagues in other parts of the world, and to suffering humanity to discuss these questions, and to give the world the benefits of our conclusions." Here in our own country we have the opportunities and the men to support and prepare a journal of tropical medicine, that will be the equal of any now issued." We understand it is the purpose of the society to establish such a journal in the near future.

Making Manila Healthy.—Surgeon-General O'Reilly has received a report showing a steady decrease in the death rate of the city of Manila as a result of the work of army medical officers. The death rate has decreased steadily from 46.80 per 1,000 for the first quarter of 1900 to 22.17 for the first quarter of 1903. Assistant Surgeon Munson says the improvement has been accomplished in spite of Asiatic cholera and bubonic plague and the existence of a largely unvaccinated population in the provinces. Cases of plague, cholera and smallpox have occurred in Manila during the present year, but precautions taken by the board of health have prevented an epidemic. Attention is called to the fact that the present annual mortality in Manila, 22.17 per 1,000, is lower than that of many cities not commonly regarded as unhealthful situated in the United States and elsewhere. According to Dr. Munson, the present death rate of Manila compares not unfavorably with those of San Francisco, Boston, New York, Glasgow, Paris, Vienna and Havana.

Factors in Spreading Typhoid Fever.—During 25 years, reports to the State Board of Health showed that typhoid fever existed in Michigan inversely as the depth of water in wells. Recently there has apparently been a marked change in this relation. From March 1 to June 30, 1903, the average depth of water in the observation well at Lansing has been over twice as much, and the typhoid fever over 80 per cent. more prevalent than the average for the ten years preceding. The unusual spread of typhoid fever in Michigan, notwithstanding the existence of conditions which hitherto favored its decline, may be due to several facts—such as that one circuit judge has decided that typhoid fever is not a communicable disease, dangerous to the public health, and some boards of supervisors have refused to allow bills for expenses incurred by local health officials for the care of indigent typhoid fever patients, thus practically putting a stop to local work, by health officials, for the restriction of typhoid fever in those parts of the state. In cities, especially in Menominee, typhoid fever is and has been a great factor in the mortality rate. Even the Detroit Board of Health takes no action to require reports from householders and physicians, or other measures for the restriction of this dangerous communicable disease, such as placarding of premises, disinfection of discharges, and of premises after death or recovery of patients.

CANADA.

Acid in Canned Meats.—The analysts of the Inland Revenue Department of the Canadian government at Ottawa, have just completed an analysis of 99 samples of canned meats. Of these 94 were all in good condition. One spoiled sample contained boric acid, and with this exception all the other samples were found to be in good condition. The only preservative discovered was boric acid, which was found in 21 samples. In no case did the quantity of boric acid found exceed the limit fixed by the British parliamentary commission, viz., .05 per cent., and in most cases it fell markedly below that standard.

The Medical Curriculum in Ontario.—At the beginning of the session of 1902-03 in the Ontario medical colleges considerable concern was manifested over the action of the Ontario Medical Council for last year in raising the standard of matriculation in this province. The Ontario Medical Council has just held its annual meeting in Toronto. It was a new council as the territorial elections had been held since last they met, and several of the old councilors had fallen in the battle. This matter of matriculation came up for considerable discussion, and was referred to a small select committee, which is to report on the subject next year. This will ensure full consideration of a difficult matter. For the first time in its history the council has adopted measures which permit the various medical teaching institutions to exercise their own discretion in determining the time which is to be allotted to instruction in a subject of the curriculum. That the customary action of the council on this point is abandoned is of great significance, for it will help very considerably in the project, now almost consummated, of building up one great medical faculty in Toronto.

Keeping Out Undesirable Immigrants.—The immigration policy of the Canadian government has recently been much discussed in parliament. Members of parliament have complained that the present policy does not look sharp enough after such minor diseases as lupus and trachoma; and they have insisted that the Canadian government ought to make arrangements with the government of the United States for mutual action in reference to the inspection of immigrants. The Canadian government immigration policy makes no provision to keep out criminals or paupers, with the result that many undesirable immigrants are permitted to find homes in Canada. During the season of 1902 4,986 persons were inspected at the port of Montreal by the United States officers, and of this number 2,028 were rejected. Of this number 419 were rejected because they were contract laborers, 812 were paupers, 8 idiots, 5 ex-convicts and 496 as having loathsome and contagious diseases. These were all dumped on Canadian soil, and none of them had been deported by the Canadian government. The statement has appeared in an editorial in a leading daily that many of our foreign-born patients in our insane asylums have been in similar institutions before coming into Canada. A comparison of Canadian and American inspection goes to show that the quality of Canadian immigration should in future be more carefully maintained.

FOREIGN.

Sir Frederick Treves will retire from active practice, it is announced in the English newspapers.

Cuba Has Little Yellow Fever.—Only three cases of yellow fever have come into Havana this year, all from Mexican ports.

The plague in Chili is spreading, having occurred in several cities, including Valparaiso. Smallpox is also spreading and occasioning much alarm.

Kraepelin Goes to Munich.—Professor Kraepelin of Heidelberg has accepted a call to Munich to the chair of psychiatry left vacant by the death of Anton Bumm in April.

Physicians in the German Reichstag.—The new Reichstag will contain seven medical members, including Drs. Mugdan of Berlin, Leonhart of Kiel and Ruegenburg of Bonn. All but two were elected by different political parties.

London Burdened with Mosquitoes.—The suburbs of London along the Thames, below the city, are said to be scourged with mosquitoes, so that outdoor life in the evening is a burden. The cause is not mentioned in the press despatches.

How Many Miles Does the Blood Travel?—The *Riforma Medica* states that with about sixty-nine pulse beats to the minute the blood flows a distance of seven miles an hour. This is equivalent to 61,329 miles a year, and in a man 84 years of age to 5,151,636 miles during the course of his lifetime.

Prize for Joannovics of Vienna.—The Brussels Académie de Médecine has awarded to Dr. G. Joannovics, assistant at the Vienna Institute for General and Experimental Pathology, the prize of $200 offered for the best work based on new experimental researches. His subject was "The Pathogenesis of Icterus."

Panhellenic Congress.—The second annual congress of Greek-speaking members of the profession was held at Athens, May 17 to 23. About 95 of the 350 members in attendance were from the countries farther east. The communications were so numerous that they required ten sessions to complete the program.

Paris Zambaco Prize.—This prize, offered by the French Society of Dermatology, was not awarded this year but an "encouragement" of $70 was given to Messrs. Bezançon, Griffon and Le Sourd for their monograph on "Bacteriology of Simple Chancre," and to Messrs. Carle and Meynet for one on "Digestive Disturbances in Eczema."

An Anti-Mosquito Plant.—Captain H. D. Larymore describes in the London *Times* a plant found in the Niger district which attracts and stupefies mosquitoes. One of these plants grow-

ing in a room frees it of mosquitoes and protects against malaria. He has officially reported the existence of the plant to the authorities at Kevy, the capital of the district.

Medical Sea Voyage.—Dr. G. Hirte of the Rheineck sanatorium at Nieder-Walluf a. Rh., Germany, will repeat this year the medical sea voyages with patients which proved so successful last spring. The first voyage will be to Buenos Ayres or Brazil and is expected to last two months or two months and a half. On his return he will start for Japan with another party for a three to four months' trip.

Proceedings of the Prussian Medical Court of Honor.—This peculiar German official institution described in The Journal, has had 211 cases before it during the last fiscal year. Of this number the complaints came from government officials in 25 instances, from physicians in 110, from the lay public in 25, and 4 were anonymous. About 80 of the suits were dismissed, 26 were compromised, in 14 a penalty or reprimand was imposed and 81 suits are still pending.

Post-Graduate Headquarters at Berlin.—Nearly $315,000 has been collected for the proposed headquarters for post-graduate medical instruction to be established in Berlin. It is to be known as "the Empress Frederick House," and from this center all the paraphernalia necessary is to be despatched to various small towns or villages as needed. These free traveling post-graduate courses which have been established in the last year or two in Germany, have already become a prized feature of German medical life.

The Radium Cancer Cure.—Considerable interest is reported to have been excited in Vienna medical circles by reports of cancer cured by exposure to the rays emanating from the remarkable substance, radium. This was mentioned editorially July 11. Now Dr. Mackenzie Davidson of Charing Cross Hospital, London, reports a case of cancer of the nose cured by the same means. Four exposures, aggregating an hour altogether, were given at intervals of a few days. In three weeks healing was progressing satisfactorily, and in six weeks the growth was all gone.

Suspension of "Memorabilien."—For forty-four years this medical journal has been published at irregular intervals of from one to several months. Dr. F. Betz of Heilbronn has been the publisher and editor and Dr. Guido Bell of Indianapolis the American collaborator. It has been principally devoted to abstracts and has borne as its motto: "Sometimes the smallest ache is the index to diagnosis and therapeutics." Dr. Betz does not care to continue the journal further, and announces its suspension with the close of 1902.

Contract Practice at Bourg, France.—The physicians of this town of 18,000 inhabitants—14 in all—found that the sickness benefit societies were materially decreasing their income while the rates paid—20c. a visit, day or night—were too low. When they asked for 40c. for an office consultation and 60c. for a call at the residence, with a reduction of 20 per cent. on the total when the bill was paid before a certain date, the societies were incensed and denounced them, and are doing their utmost to induce other physicians to move to the town and accept their rates, ignoring the physicians already settled there. To date they have been unable to do this, and our French exchanges are warning the profession at large not to "pick up the bone which the local physicians have found too bare."

Correspondence.

Regarding "The Boy's Venereal Peril."

New York, July 16, 1903.

To the Editor:—Since publication of the above-mentioned article, I have received requests for 2,090 reprints thereof. Pressure of practice renders me unable to reply individually to each one of the gentlemen who wrote me on the subject. I therefore ask the privilege of using your columns to answer all.

1. The kind sentiments which my correspondents convey stimulate me to greater efforts than ever before, so to revise the article that it may represent the best work of which I am capable. I need not tell other busy practitioners that I can not do this within the next few days. I expect, however, to have the reprints ready in about three weeks.

2. A number of those who have favored me, ask for "some" or "several" copies. If they will kindly specify how many they desire I will know how large an order for reprints I must give.

3. Many of my correspondents ask me the price of the reprints. Having written the paper to benefit humanity as much as is in my power, I do not desire to profit thereby. Moreover, being engaged exclusively in genito-urinary work, I have no inclination to earn money otherwise.

4. It is beyond my power to grant licenses to reprint "The Boy's Venereal Peril." The copyright rests with the American Medical Association, which owns all papers presented before it.

5. The paper as published in The Journal of the American Medical Association is incomplete; one reason therefor is in the fact that the remainder, being addressed to boys, is too elementary for appearance in a scientific publication. I therefore requested its omission.

6. The reprints will not contain my name or address or anything else to reveal my authorship. This will prevent such laymen as may be advised to read the paper from confounding it with the advertisements of quacks.

7. Lack of time prevents my undertaking to deliver messages, to ascertain the prices of books and other articles, or to make purchases for some of those who wrote me regarding "The Boy's Venereal Peril."

I repeat my sincere thanks to all those who gave such kind encouragement to this one of my efforts.

Ferd. C. Valentine.

Historical Errors.

Chicago, July 20, 1903.

To the Editor:—In The Journal of the American Medical Association, July 18, 1903, p. 195, it is stated, under the head of deaths, that the late Dr. DeLaskie Miller of Chicago was "born in New York City," graduated from "Syracuse Medical College in 1842," which is evidently erroneous. According to reliable authority Dr. Miller was born in Niagara County, New York, May 29, 1818, and graduated from Geneva Medical College, New York, in 1842, there being at that date no medical college in Syracuse.

On page 196 of The Journal it is stated that the New Jersey State Medical Society was organized in 1776, which is evidently erroneous. According to reliable authorities that state society, the oldest in the country, was organized in 1766, and held its meetings annually until they were interrupted by the Revolutionary War in 1776; but they were resumed as early as the exigencies of the war would permit. N. S. Davis.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

WHAT IS IT?

Castroville, Texas, July 11, 1903.

To the Editor:—I wish information about a peculiar epidemic we have had here for several months. Nothing in the literature at my command helps me. We have had malaria here for three years, known to me by examination of the blood, generally examined while fresh, and showing the plasmodium and spores, and in each case the margin of the tongue shows some minute red spots, very noticeable, being of different color from the surrounding membrane and varying from a half dozen to several dozen. The other symptoms are very variable, from high fever (103 F. to 99 F.) every other day, headache, sometimes a distinct chill and sometimes not, neuralgias or abdominal pains, in fact all somewhat differently effected, but whenever the tongue showed these spots the blood showed plasmodium and spores. Quinin or methylene blue gave relief and in several instances cured the symptoms, but also in several instances the plasmodium and spores continue in the blood in spite of the continued use of quinin mixed with either arsenic or iron or both, etc. Now things have changed in respect to symptoms, although I have still, among adults, occasional cases with the above symptoms, but children here have developed a cough due to a pharyngitis with relaxed uvula that very closely simulated whooping cough; some last about a week and some are still coughing after six weeks; and now, to confuse the thing more, an erythema has developed, accompanied by fever, 102 F. or so. It is scarlatiniform in appearance, yet there is an accompanying cough and conjunctivitis and very mild coryza. The rash

lasts from two to three days, and fades when fever is low, with no desquamation, no enlarged glands and no albumin in the urine, but spores and plasmodium in the blood and the spots before mentioned on the outer margin of the tongue, which, at the same time, shows in some cases enlarged papilla. We have had scarlet fever, measles, German measles and whooping cough here, but this does not fully represent any one of them, yet resembles them all in some cases, or, rather, some one of them more particularly. I am forced to believe it is malarial. Very fortunately so far there have not been any deaths, and the bronchitis very mild that accompanies or, rather, follows the rash. I have tried to describe the condition, but it is hard; some have the cough and no rash, some rash and little cough, some itch and some do not, and the more I consult the record I have been keeping, the more confused I get when I try to compare the symptoms with any of the (to me) known diseases.

JOHN T. FITZSIMON, M.D.

State Boards of Registration.

New Medical Provisions in the Virginia Law.

The legislature of Virginia has passed the following amendments to the medical practice act:

1. Be it enacted by the general assembly of Virginia that section seventeen hundred and forty-seven of the Code of Virginia, as amended and re-enacted by an act approved March 7, 1900, be amended and re-enacted so as to read as follows:

1747. *Examination of Applicants for the Practice of Medicine and Surgery; Re-examination; Fees of Board.*—It shall be the duty of the said board, at any of its said meetings, to examine all persons making application to them, who shall desire to commence the practice of medicine or surgery in this state, provided said applicant shall produce before said board a diploma or other satisfactory evidence of his graduation in some medical college or institution teaching the art of healing human diseases chartered by the state or territory in which the same is situated; provided, that any undergraduates taking a graded course in any regularly chartered medical school shall be entitled to examination on such branch or branches as he or she may present a certificate from the said college of having passed a satisfactory examination, and having once passed a satisfactory examination on each of such branches before the State Board of Medical Examiners no further examination shall be required on such branch or branches; but an applicant failing to pass a satisfactory examination on any of such branches shall not be permitted to be examined on such branch or branches until he or she presents a diploma of graduation as doctor of medicine from some regularly chartered college of medicine. And when an applicant shall have passed an examination satisfactory as to proficiency before the board in session, the president thereof shall grant to such applicant a certificate to that effect; provided, however, that any applicant professing a system of medicine which does not require the use of drugs in the treatment of disease shall be exempt from standing an examination of materia medica.

A fee of ten dollars shall be paid to said board, through such officers or members as it may be designated, by each applicant before such examination is held. And in case any applicant shall fail to pass a satisfactory examination he shall not be permitted to stand any further examination within the next six months thereafter, nor shall he have again to pay the fee prescribed as aforesaid; provided, however, no applicant shall be rejected on his examination on the account of his adherence to any particular school of medicine or system of practice, nor on account of his views as to the method of treatment and care of diseases; and provided, further, that when, in the opinion of the president of the board, any applicant has been prevented by good cause from appearing before the board, he shall have authority, in his discretion, to grant a special permit to such applicant to practice medicine or surgery until he shall have an opportunity to appear before the board in session for examination, which said special permit shall be revocable at the discretion of the president; and in no case shall it entitle the holder thereof to practice after the next regular meeting of said board.

The said board shall have, in their discretion, authority to accept in lieu of examination of an applicant a diploma or other satisfactory evidence of the graduation of the applicant in some medical college chartered by the state or territory in which the same is situated, and a certificate from the examining board of any state or territory of the United States or the District of Columbia, showing that said applicant has passed a satisfactory examination as to his proficiency, and obtained license from said board to practice medicine and surgery in said state, territory or district; provided, that any person who was examined by the state examining board prior to Jan. 1, 1900, and whose fee for such examination was only paid, but who failed to pass said examination, shall have the right and privilege of taking the examination before the state board, notwithstanding the provisions of this act.

2. This act shall take effect from its passage.

Approved April 23, 1903.

Be it enacted by the general assembly of Virginia that section seventeen hundred and fifty of the Code of Virginia, as amended and re-enacted by an act approved March 7, 1900, be amended and re-enacted so as to read as follows:

1750. *Who Prohibited from Practicing Medicine or Surgery without Certificate; Penalty for Practicing Illegally; What Courts Have Jurisdiction to Inflict.*—No person who shall have commenced the practice of medicine or surgery in this state since Jan. 1, 1885, or who shall hereafter commence the practice of the same, shall practice as a physician or surgeon for compensation without having first obtained a certificate from the State Board of Medical Examiners and cause the same to be recorded as aforesaid, or a special permit from the president of the said board. To open an office for such purpose or to announce to the public in any way a readiness to practice medicine in any county or city of the state, or prescribe for, or to give surgical assistance to, or to heal, cure or relieve, to attempt to heal, cure or relieve those suffering from injury or deformity, or disease of the mind or body, or to advertise, or to announce to the public in any manner a readiness or ability to heal, cure or relieve those who may be suffering from injury or deformity, or disease of the mind or body, shall be to engage in the practice of medicine within the meaning of this section; provided, that nothing in this section shall be construed to apply to or to limit in any manner the manufacture or sale of proprietary medicines, or apply to, affect or interfere in any way with the operation of any hospital now established in this state, or any person while engaged in conducting such hospital now established, if there be a licensed physician resident and practicing therein, or to any person who commenced the practice of osteopathy in this state prior to Jan. 1, 1903.

It shall also be regarded as practicing medicine within the meaning of this section if any one shall use, in connection with his or her name, the words or letters "Dr.," "Doctor," "Professor," "M.D." or "Healer" or any other title, word, letter or designation intending to imply or designate him or her as a practitioner of medicine or surgery in any of its branches; but this section shall not be construed to apply to non-itinerant opticians who are at this time engaged in the practice of optometry in this state nor to professional or other nurses. Any person who shall practice medicine or surgery in this state in violation of the provisions of this section shall be fined not less than $50 nor more than $500 for each offense; and it shall not be lawful for him to recover by action, suit, motion or warrant in any of the courts of the state any compensation for services which may be claimed to have been rendered by him as such physician or surgeon. The county and corporation courts shall have exclusive original jurisdiction to try offenses for violations of the provisions of this section committed within their respective counties and corporations.

2. This act shall take effect from its passage.

Approved April 24, 1903.

This, as the *Old Dominion Journal* remarks, applies to faith healers, Eddyites, osteopaths, etc., all of whom must pass the examination if they pose as healers.

Deaths.

Herman Nauman, M.D. University of Jena, Austria, 1851, a pioneer physician of Milwaukee, surgeon of the Ninth Wisconsin Volunteer Infantry in the Civil War, formerly county physician of Milwaukee County, and in charge of the Marine Hospital, died at his home in Milwaukee, July 4, aged 79.

Samuel J. Radcliffe, M.D. University of Georgetown, D. C., 1852, a veteran of the Civil War, in which he served as medical director, a member of the Medical Society and Medical Association of the District of Columbia, died at his home in Washington, July 9, after an illness of seven months, aged 75.

George R. Wells, M.D. Rush Medical College, Chicago, 1886, of Livingston, Mont., died at Bethany, N. Y., July 10, from the effects of chloroform, self-administered, presumably for the relief of spinal pain, aged 41. He was a member of the American Medical Association.

William C. Bailey, M.D. Berkshire Medical College, Pittsfield, Mass., 1844, assistant surgeon of the 179th N. Y. Volunteer Infantry in the Civil War, and a resident of Adams Center, N. Y., for half a century, died at his home in that place, July 6, aged 77.

Joseph S. Cook, M.D. University of Pennsylvania, Philadelphia, 1856, surgeon of the 31st N. J. Volunteer Infantry in the Civil War, died at his home in Washington, N. J., July 4, from hypostatic pneumonia, after an invalidism of thirteen years, aged 73.

Nathan F. Brown, M.D. Detroit Medical College, 1870, a veteran of the Civil War, and a member of the Michigan State Medical Society and the American Medical Association, died at his home in Detroit, July 6, after years of ill health, aged 66.

Robert Black Ewing, M.D. University of Pennsylvania, Philadelphia, 1865, a member of the American Medical Association, and for nearly forty years in practice at West Grove, Pa., died at his home in that place, July 3, from heart disease, aged 62.

R. B. Parker, M.D., inspector on the steamer *Mount Vernon*, died from yellow fever at the government quarantine station, Ship Island, Miss., July 6, from yellow fever, with which he was stricken on his first trip to Costa Rica.

Richard W. S. Martin, M.D. Medical College of Virginia, Richmond, 1861, a member of the Lauderdale County Medical Society, died at his home in Henning, Tenn., after an illness of three years, from dropsy, July 16, aged 63.

Alonzo Garwood, M.D. Starling Medical College, Columbus, Ohio, 1850, the oldest practitioner in Cass County, Mich., died July 1, from heart disease at his home in Cassopolis, aged 78. He retired from active practice in 1901.

Charles Thomas Van Swearingen Butler, M.D. University of Maryland School of Medicine, Baltimore, 1874, of Shepherdstown, W. Va., died at the Winchester (Va.) Memorial Hospital, July 8, aged 53.

Bernard S. Simpson, M.D. St. Louis Medical College, 1897, professor of physical diagnosis in the St. Louis College of Physicians and Surgeons, died July 1 at his home in St. Louis, aged 30.

Marcella C. Baldwin, M.D. Woman's Medical College, Chicago, 1882, of Rockford, Ill., died from tuberculosis at St. Anthony's Hospital, Rockford, July 7, after an illness of eight years, aged 45.

Frank W. Morley, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1884, died from inflammation of the brain at his home in Sandusky, Ohio, July 4, after a brief illness, aged 42.

W. V. Hawthorne, M.D. Medical Department University of Tennessee, Nashville, 1902, of Watertown, Tenn., died suddenly at Hot Springs, Ark., Oct. 4, 1902, aged 39.

Samuel A. Bowen, M.D. Barnes Medical College, St. Louis, 1897, died at his home in Corinne, S. C., July 4, from typhoid fever, after an illness of three weeks.

Louis A. Falligant, M.D. Hahnemann Medical College, Philadelphia, 1858, died suddenly at his home in Savannah, Ga., July 5, from heart disease, aged 66.

G. Paul Jones, M.D. Jefferson Medical College, Philadelphia, 1869, died suddenly from apoplexy at his home in Princess Anne, Md., July 6, aged 61.

James Alfred Perkins, M.D. University of Maryland, Baltimore, 1854, of Chestertown, Md., died suddenly at Germantown, Pa., July 7, aged 71.

Arthur H. Barr, M.D. Tulane University, New Orleans, 1900, of Starkville, Miss., died at San Angelo, Texas, July 6, from pneumothorax.

Willis D. Hamilton, M.D. University of Pennsylvania, Philadelphia, 1890, died at his home in Kennett Square, Pa., July 3, aged 36.

Emma H. Yates, M.D. Fort Worth (Texas) University, 1899, died at her home in Ander, Texas, June 12, from tuberculosis.

C. W. Hinchman, M.D. American Medical College, St. Louis, 1885, died at his home in Golden City, Mo., July 7, aged 72.

Frank Buys, M.D. Western Reserve University, Cleveland, 1885, died at his home in Painesville, Ohio, July 2.

T. J. Caldwell, M.D., died at his home in Lannius, Texas, July 3, from paralysis, aged 74.

William Van den Berg, M.D., 1849, died July 6 at his home in Zeeland, Mich., aged 77.

Book Notices.

THE DIAGNOSIS AND MODERN TREATMENT OF PULMONARY CONSUMPTION, with Special Reference to the Early Recognition and the Permanent Arrest of the Disease. By Arthur Latham, M.A., M.D. Oxon., M.A., Cantab., Author of the Prize Essay on the Erection of His Majesty's Sanatorium. Cloth. Pp. 215. Price, $1.50 net. New York: Wm. Wood & Co. 1903.

Our readers are probably aware that in the competition for the plans of the King Edward VII sanatorium the prize was awarded to Dr. Arthur Latham, assistant physician at the Brompton Hospital for Consumption and Diseases of the Chest. Dr. Latham has brought together a series of articles which he has published during the last few years, especially on the diagnosis and treatment of pulmonary diseases, and with especial reference to the sanatorium treatment. He has contributed a valuable memoir to the literature of this at present very much written up disorder. The book is well arranged, and contains a large amount of practical information. The author does not seem to have much faith in the opinion that there is danger in the marriage of tuberculous individuals as far as direct contagion is concerned, or of transmission to the offspring, and he thinks that by marriage tuberculous individuals are often enabled to lead a more regular life and avoid some of the more dangerous vicissitudes that threaten them. One of his concluding remarks, that the wise physician never gives a prognosis in cases of tuberculosis, is an excellent one. The disease is not one that is directly amenable to prognosis, especially when all proper means of treatment are available, and the most desperate cases sometimes recover.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, United States Army. Authors and Subjects. Cloth. Pp. 894. Second Series. Vol. VIII. Insane—Kysthospitalet. Washington: Government Printing Office. 1903.

The eighth volume of the Index-Catalogue includes the literature from Ins to Kyst, and, like its predecessors, is the most valuable summary of bibliography we have within its alphabetical limits. There is nothing else of which we know that can fill the place of the Index-Catalogue in its first and second series. It is a most creditable monument to the United States Government's interest in the general welfare of mankind.

Miscellany.

Medical Education.—The profession of medicine need not feel shame at any inquiry into the character of its regular practitioners, but only the self-satisfied among us would assert that even a higher level may not be attained. Considering the matter from the view-point of the profession, nothing could be more wholesome than a high standard of requirement for admission to membership in a body that has always been regarded by the public as one of general culture and intelligence. The country has grown rapidly and the medical curriculum has become exacting. Not unnaturally, therefore, some men have entered the profession without sufficient preliminary training. It is but natural to suppose that the exactions of the medical schools and the state boards of examiners will increase rather than decrease.—*Pennsylvania Medical Journal.*

The First Case of Appendicitis.—Dr. Howard A. Kelly of Baltimore, according to the *British Medical Journal* of July 4, has greatly delighted our French brethren by giving the credit of the first clear description of a case of appendicitis to a French surgeon. Speaking in French to the Société de Chirurgie, he said that in the *Journal de Médecine, de Chirurgie et de Pharmacie*, Mestivier in 1759 reported the following case: A man, aged 45, presented himself at the Saint André Hospital, Bordeaux, for treatment of a tumor situated near the umbilical region on the right side. The surgeon made an incision, giving issue to about a pint of pus of bad quality. The patient died. At the necropsy the cecum presented nothing extraordinary. The same could not be said as regards the vermicular appendix. There was found a large pin all crusted over and eroded. It may be inferred that this pin had been long imprisoned in the appendix, and had there set up the symptoms of the disease and caused death. A few years later, in 1776, a medical student named Joubert Lamotte published a report of a necropsy in a person who had died of tympanites. The author, after describing the symptoms of the illness, states that he had found in the vermiform appendix a foreign body as it were petrified, and in the cecum entire cherries. The necropsy having been made in September the cherry season was long past. The cherries had therefore remained in the cecum, and the petrified body is the first example of fecal calculus. The first case in the nineteenth century was published by Jadelot in 1808. In 1812 a case was published in England, and in 1813 another in France by Wegeler. In 1824 appeared a paper by Louyer-Villermay, entitled "Observations to Serve for the History of Inflammations of the Cecal Appendix." In this paper are related two typical cases, in each with a necropsy. It is unquestionable, therefore, says Dr. Kelly, that to Louyer-Villermay belongs the honor of having been the first to point out the importance of appendicular inflammation. Three years later, in 1827, Melier published a memoir on the subject, based on a case of his own, and a study of the two others related by Louyer-Villermay, and on two new ones. He described the lesions in the appendix, and had even a notion of the possibility of surgical intervention. Melier had, unfortunately, no official position, and apparently little confidence in himself. His ideas did not find favor with Dupuytren, then the sovereign authority in French surgery; otherwise one of the most brilliant triumphs of modern surgery might have been achieved 70 years earlier than it was. This is one of the many examples of the disastrous influence of the superior person on the progress of science.

Association News.

The Committee on Medical Legislation of the American Medical Association.

The Committee on Medical Legislation of the American Medical Association met at the Holland House, New York, June 7, 1903. The following was adopted:

Resolved, By the Committee on Medical Legislation of the American Medical Association, that by virtue and in pursuance of the authority vested in it to devise means for the better promotion of needed legislation relative to the public health and to the medical profession, it hereby creates a committee,

First. To be known as the National Auxiliary Congressional and Legislative Committee of the medical profession of the United States.

Second. To consist of one legally qualified practitioner of medicine in each county of each state and territory of the United States and in the District of Columbia.

Third. To be appointed by the Committee on Medical Legislation of the American Medical Association on nomination by the president of each state and territorial medical association.

Fourth. It shall be the duty of each member of the National Auxiliary Congressional and Legislative Committee to bring all and only such matters of pending legislation as may be referred to him, either by the legislative committee of his respective state or territorial medical association or by the Committee on Medical Legislation of the American Medical Association, to the attention of the medical profession and the people of his respective county, and by every honorable means, personal and political, individual and professional, private and public, direct and indirect, secure desired action thereon by his representatives in both branches, as the case may be, of the state legislature or of the Congress of the United States. And it shall be his further duty promptly to report all such efforts on his part, first, relative to state legislation, to the chairman of the committee on legislation of his state medical association, and, secondly, relative to national legislation, to the chairman of the Committee on Medical Legislation of the American Medical Association.

Resolved, That the chairman of Committee on Medical Legislation of the American Medical Association is hereby directed (*a*) to procure from the president of each state and territorial medical association nominations for such National Auxiliary Congressional and Legislative Committee: (*b*) to formulate a list of the chief executive and legislative officers of the United States government and of the government of each state and territory: (*c*) to collate necessary information relative to the executive and legislative departments of the American Medical Association and of each state and territorial medical association; (*d*) to formulate a list of the officers of each state and territorial board of health and medical licensing board and (*e*) to secure a brief summary of proposed legislation, state and national. And he is further directed to arrange the information thus collected into a Congressional and Legislative Directory of the American Medical Association.

Resolved, That these proceedings, together with the Congressional and Legislative Directory above indicated, be published as the *ad interim* report of this committee, first, by installments in THE JOURNAL of the American Medical Association, and subsequently in book form, the latter to be issued in anticipation of the congressional and legislative season of 1903-4.

By the Committee,

CHARLES A. L. REED, Chairman.

Medical Organization.

Hill County (Texas) Medical Society.

The physicians of Hill County met at Hillsboro, July 11, and organized in conformity with the plans of the state and National associations.

Polk County (Ark.) Medical Society.

The physicians of Polk County met at Mena, June 18, and organized a county medical society with the following officers: Dr. Walter L. Magness, president; Dr. L. B. Sutherland, vice-president; Dr. Philip R. Watkins, secretary, and Dr. William P. Parks, treasurer, all of Mena.

Santa Rosa County (Fla.) Medical Society.

On call of Dr. J. Harris Pierpont, Pensacola, councilor for the district, the physicians of Santa Rosa County met at Milton, July 3, and organized a county medical society, with Dr. Charles E. McDougall, president; Dr. Wm. Austin Mills, vice-president, and Dr. Henry E. Eldridge, secretary and treasurer, all of Milton.

Whitley County (Ind.) Medical Society.

Dr. Albert E. Bulson, Jr., Fort Wayne, councilor for the 12th congressional district, met the physicians of the county at Columbia City and organized a county medical society on the basis suggested by the American Medical Association. Dr. Oliver V. Schuman was elected president; Dr. Frederick G. Grisier, secretary, and Dr. William F. King, treasurer, all of Columbia City.

Bexar County (Texas) Medical Society.

Physicians of Bexar County met at San Antonio, July 9, and organized a county medical society. The constitution and by-laws as outlined by the American Medical Association and endorsed by the Texas State Medical Association were adopted. The following officers were elected: President, Dr. Thomas T. Jackson; vice-president, Dr. William M. Wolf; secretary, Dr. Thomas E. Moore; and censors, Drs. John S. Lankford, Dabney, Berrey, and William E. Luter, all of San Antonio.

Webster County (Iowa) Medical Society.

On June 27, on call of Dr. Charles H. Churchill, councilor for the tenth district, a meeting was held at Fort Dodge to organize a county medical society. The constitution and by-laws recommended by the American Medical Association were adopted. The following officers were elected: President, Dr. Robert Evans, Fort Dodge; vice-president, Dr. Orville E. Evans, Gowrie; secretary, Dr. William W. Bowen, Fort Dodge, and treasurer, Dr. Floyd B. Olney, Fort Dodge.

Wright County (Minn.) Medical Society.

Physicians of Wright County met at Buffalo, July 2, and organized a county medical society, according to the plans of the state and National organizations. Dr. Edwin Y. Chilton, Howard Lake, was elected president; Dr. Albert F. Lynch, Monticello, vice-president; Dr. Edward A. Shannon, Buffalo, secretary, and Dr. G. M. F. Rogers, Buffalo, treasurer. Drs. Theodore J. Catlin, Delano; Arthur L. Hill, Monticello, and Timothy O'Connor, Maple Lake, were elected censors.

Societies.

Santa Clara County (Cal.) Medical Society.—At the annual meeting and banquet held in San Jose, June 17, the following officers were elected: President, Dr. William T. McNary, San Jose; vice-presidents, Drs. James T. Harris, San Jose, and David A. Beattie, Santa Clara; secretary, Dr. J. L. Asay, San Jose, and treasurer, Dr. William D. McDougall, San Jose.

Yale Medical Alumni Association.—The annual meeting and banquet were held in New Haven, June 22, at which the following officers were elected: Dr. J. Francis Calef, Middletown, Conn., president; Drs. Frederick B. Sweet, Springfield, Mass., W. S. Miller of Michigan, Edward W. Goodenough, Waterbury, Conn., Homer T. Partree, Blandford, Mass., and John Edward Lane, Hadley, Mass., of the class of 1903, vice-presidents.

Sioux Valley Medical Association.—The semi-annual session was held at Fort Dodge, Iowa, June 26. The following officers were elected: Dr. Van Buren Knott, Sioux City, Iowa, president; Drs. Charles H. Churchill, Fort Dodge, Iowa, and Frederick A. Sedlacek, Tyndall, S. D., vice-presidents; Dr. Maxwell E. Silver, Sioux City, secretary (re-elected), and Dr. Samuel A. Brown, Sioux Falls, S. D., treasurer. Sioux City was selected as the meeting-place in January, 1904.

Alumni Association of the Medical Department of the University of Texas.—The annual meeting was held in Galveston, May 30, at which the following officers were elected: President, Dr. John T. Moore, Galveston; vice-presidents, Drs. H. B. Decherd, and C. D. Cantrell, Galveston, and Miss M. Giddings, Brenham; secretary, Dr. Herbert F. Sterzing, Austin; treasurer, Dr. H. O. Sappington, Galveston; orator, Dr. S. H. Grant, Rugby, and alumni editor, Dr. Louis H. Kirk, Austin.

GERMAN GYNECOLOGICAL ASSOCIATION.

Tenth Congress, held at Würzburg, June 3 to 6, 1903.

The President, Professor Hofmeier, in the Chair.

The questions appointed for discussion were: Extrauterine Pregnancy and Prolapse Operations.

Extrauterine Pregnancy.

The addresses on the first subject were by J. Veit of Erlangen and Werth of Kiel, who discussed both the anatomy and treatment. Veit attributes the severe hemorrhage into the abdominal cavity in case of ruptured tubal pregnancy to the deportation of villi. If a vein beneath the peritoneum becomes filled with villi the blood current is arrested and the vein ruptures. When the rupture occurs the resistance at this point is

less and the blood pours freely in this direction. The ovum is detached as a result of the stagnation of the blood current, and blood also escapes from the points where it has been attached. In abortion in the uterus the contraction of the walls tends to arrest the bleeding, but there is no contraction in tubal abortion, and the hemorrhage continues unchecked. He maintains the possibility of tubal abortion, that is, violent hemorrhage into the abdominal cavity without rupture. He prefers incision to exploratory puncture, and operates when the fetus is still in the tube, but if it has escaped from the tube he waits as long as possible. If impossible to distinguish he is guided by the severity of the symptoms. The ideal is the complete extirpation of the fetal sac. In case of suppuration, however, it is certainly better to suture it in. He chooses the vaginal route only in case of fever, and then only incises the sac. Werth thinks that the results of active and conservative treatment about balance.

In conclusion, he made an earnest plea for stricter concentration of research in the domain of ectopic pregnancy, and the restriction of the literary over-production which is spreading over wide surfaces without going deep. This over-production renders it more and more difficult for one to keep posted on the subject, and is a direct hindrance to scientific progress, for in the overwhelming mass of long-established facts which are simply brought forward and published over and over again, the really new and important results of original research are easily overlooked by those especially interested in the subject.

Sarwey, Tübingen, from an experience of 71 cases of extrauterine pregnancy believes that colpotomy should be restricted to cases of uncomplicated tubal moles without hematocele, or suppurating and purulent hematoceles.

Strassmann, Berlin, with an experience of 20 cases, urges laparotomy for every case of severe hemorrhage, or of dubious diagnosis or lack of after-care in a clinic. He warns that the uterus must never be drawn forward; it must always be able to be pushed upward. This warning was endorsed by others.

Jung, Greifswald, does not agree with Veit that it is best to wait if the fetus is dead, and operate only on renewal of symptoms. The conditions in the latter case are much less favorable for an operation. Long-continued absorption impairs the working capacity and the case frequently terminates in perimetritis. In his 86 cases he operated through the abdomen in 43, and through the vagina in the same number, with 2 deaths in each category. He always operates unless particularly favorable external conditions exist or there is reason to expect rapid absorption. He always strives to leave as much as possible of the tube or ensure the permeability of the other.

Küstner, Breslau, has operated on 154 cases of extrauterine pregnancy with a mortality of 5. He advocates exploratory puncture and reiterates that a small amount of old blood in the canula is evidence of an old extrauterine pregnancy. Wealthy women may be treated expectantly, but women of the working classes should be operated on and by the abdomen, as the formation of adhesions can thus be better guarded against.

Prolapse Operations.

The addresses on this subject were by Martin, Greifswald and Küstner, Breslau. The former ascribes the etiology of prolapse to impaired resisting power on the part of the connective tissue after pregnancy or infectious diseases or in the menopause, etc. Obstetric trauma, inflammations, tumors, are merely the incidental factor on this foundation. He does not regard pessaries as of much value for prophylaxis; the prolapse benefits as the general health improves. He advocates early operation, early reduction of the size of the vaginal protrusion and restoration of the bladder to its place. Extirpation of uterus and vagina is only exceptionally indicated, 19 times in his experience in 2,000 operations for prolapse. Küstner, on the other hand, is a partisan of pessary treatment, except for working women, for whom the ring pessary has its inconveniences. He thinks that the pessary ensures a better position than any operation. It must be worn with the uterus in a good position for a year at least, after which recurrence is rare. Treatment should be addressed principally to the retroversion; the vaginal prolapse is a secondary matter.

Ziegenspeck, Munich, has been experimenting on cadavers, trying to induce prolapse, and found it practically impossible. For this and other reasons which he enumerated, he believes that the cause of prolapse lies in the difference between the abdominal and the atmospheric pressure. When the portio vaginalis happens to lie over the opening in the floor of the pelvis, the conditions are ripe for prolapse, as it then experiences the stress of the difference in pressure and is sucked outward by the lesser atmospheric pressure.

Schauta, Vienna, described his method of treating severe cases by drawing down the uterus to the vesico-vaginal septum with extensive colpoperineorrhaphy, closing the vagina behind completely over the uterus. The important point is the strengthening of the recto-vaginal septum. Conception must naturally be prevented after this operation, and he asserts that all methods which retain the sexual function are liable to recurrence. Bumm, Halle, believes in total extirpation for women near the menopause in cases of unusually large prolapse with enterocele, of chronic metritis, erosions or ulcerations, affections of the adnexa or tumors and rebellious cystitis with cystocele. In 105 patients treated by total extirpation, 93 per cent. have regained their complete working capacity and 75 per cent. are objectively cured. His mortality has been 2 in 105, and in 176 cases reported in the literature the mortality was 6.9 per cent.

Plans for the Next Congress.

The eleventh congress will convene in 1905 at Kiel, under the presidency of Professor Werth. The special subjects appointed are: "Methods of Artificial Dilation of the Pregnant and Parturient Uterus," and "Permanent Results of Ovariotomies, with Special Reference to Tumors of Dubious Anatomy."

The association also voted by request on two subjects as suggestions for the international congress of gynecology to convene at St. Petersburg in 1905, adopting for the first, "Suture of the Abdominal walls," and for the second, "Operative Treatment of Uterine Myomata."

A detailed report of the congress appears in the *Muenchener Med. Wochft.*, June 23 and 30.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Thirteenth Annual Meeting, held at New Orleans, May 4, 1903.

(*Continued from page 201*)

Report of Committee on Revision of Constitution as to the Standard of Admission.

The motion of Dr. Geo. M. Kober, that the order of program be changed so that the symposium take precedence of the report of the special committee on revision of the constitution, was lost. (Nays, 23; yeas, 21.)

The report of this committee being called for, Dr. J. M. Dodson, in the absence of the chairman, Dr. Ritchie, offered the following majority report:

MAJORITY REPORT.

REQUIREMENTS FOR ADMISSION TO MEDICAL COLLEGES.

In presenting their report on the Revision of Article III of the Constitution, the committee deems it unnecessary to enter into a very extended argument, but it may be of advantage to call attention to a few facts in connection with the matter and to set forth their reasons for framing certain portions of the amendment as they appear.

Attention is first called to the action of the Association at Saratoga, which led to the appointment of this committee. It will be remembered that the address of President Vaughan, which, among other things, recommended an increase in the admission requirements prescribed by the Association, was referred to a committee; the following action was taken in the matter of the report of that committee. I quote from the minutes: "On motion the recommendation of the committee with reference to making the standard of admission the full equivalent of a four years' high school course and the appointment of a committee to consider this matter and to prescribe the branches to be included in this course and time to be devoted to each, was adopted. It was moved to accept the recommendation that the examination of the student (for

admission) be taken entirely out of the hands of the medical school. Motion amended to lay on the table. Amendment lost by a vote of 21 against and 13 for. The original motion to accept was then put and carried. The committee recommended that Article III, Section 3, should be amended to read 'two conditions' instead of 'two or more' conditions. This recommendation was accepted on motion. The committee further reported as follows: "The committee would recommend that a special committee of three be appointed to consider the question whether the standard of admission should not be made the full equivalent of a four years' high school course, such committee to report at the meeting of the Association next year."

"On motion of Dr. Long the report was adopted as a whole, and the committee, Drs. Ritchie, Dodson and Wathen, continued, as the special committee recommended in the report, this special committee to report at the New Orleans meeting, May, 1903."

It will be observed that the instructions to this committee by the Association at Saratoga were very explicit with regard to certain things. While the minor details of the report may, therefore, be criticised, the recommendation that the requirements for admission as laid down in Article III be made a four years' high-school diploma, or a full equivalent therefor, has already been passed on by this Association.

Previous to the organization of the Association of American Medical Colleges there was a standing committee on medical education of the American Medical Association; this committee was abolished when this Association was formed, it being understood and agreed at the time that the chief object of this Association was to elevate the standards of medical education in the United States. It is believed that this organization was a factor in elevating the standards in the early period of its existence and that, at least indirectly, it assisted in securing the statutory enactments in the several states establishing the standard of attainment for medical practice. If this be true, however, the impulse given to the several state boards of health and examining boards has carried them considerably beyond the point reached by the Association, for, at the present time at least, eight states, namely, New Hampshire, New York, Pennsylvania, Ohio, Indiana, Illinois, New Mexico and Colorado refuse to recognize colleges which do not demand a four years' high school diploma or its equivalent as a prerequisite for admission. The advance made by the state boards in this direction has been very rapid and satisfactory, and the example set in the states mentioned is very certain to be followed by others in the near future. Meanwhile, this Association has remained at a standstill for more than five years, in spite of the earnest effort to secure some action which has been made at the last four meetings.

For some reason, too, the American Medical Association seems to have concluded that it ought again to take an active part in the matter of medical education, the inference being that the status of this Association, to which were relegated all matters of medical education at the time of its organization, is not satisfactory. At the meeting in Saratoga last year a standing committee on medical education was appointed which will make a report at the session about to be held. It is not known, of course, what this report will be, but that action of some sort will be taken seems very probable. It has been intimated that membership in the Association and its constituent state and county societies should be denied to those who are connected with medical schools not up to a given standard. It would be humiliating, indeed, for this Association, if standards should be established by the American Medical Association considerably in advance of the standards of this body, which has posed as the particular sponsor for higher medical education in this country.

So far from representing the relatively high standards for which it stood at the time of its organization, its requirements are utterly inadequate to meet the demands of the profession at the present time. The Association has lost the respect of the profession, its standards are entirely discredited by the better examining boards, and it may fairly be said that it is a questionable honor for any institution to be a member of it. A position in the faculty of some of the institutions here represented is a dubious distinction.

It will, perhaps, be urged against increasing the existing requirements to the standards proposed, that it is a hardship to the poor and self-supporting students who may not have had an opportunity to secure a high school education. The reply to this criticism is obvious; in the first place, the medical college is not an eleemosynary institution designed to induce poorly-prepared young men to enter the ranks of a profession for which they are not qualified. In the second place, it is a serious injustice to such a student to allow him to take up the study of medicine. With over five thousand graduates emerging from our medical colleges annually, which is at least two thousand in excess of the demand, the competition among practitioners is keen and growing ever keener; it is not difficult to foretell that the successful men in this competition will be, with rare exceptions, those who are well equipped, and especially those whose fundamental education is the most thorough. Reasonably high requirements, therefore, are primarily in the interest of the students themselves. And, thirdly, it should be said, that the self-supporting students are the ones of all others, who can afford to spend the extra time necessary to properly prepare themselves for medical study. The student who is dependent on his parents, or some one else, for his support may well be anxious to complete his course as soon as possible that he may cease to be a burden on others and become self-supporting; to the student, on the other hand, who is paying his way as he goes, the addition of one, two, or three extra years is a matter of minor importance.

That the adoption of such standards as are proposed here would be disastrous to unendowed medical colleges, seems to your committee a most surprising argument to bring forth. For what are medical colleges established? For the benefit of the members of the faculty, or of the board of trustees who may reap some financial profit from them? Surely this is not the case. No medical school can justify its existence except on the ground that it is engaged in a work that is necessary to the community and that it is being conducted in a proper and legitimate way along lines and in accordance with the standards that are demanded by the times. If the statutes and rules of the examining boards of eight of the leading states have already established higher standards, it seems to your committee that it must be a difficult task for any faculty to maintain its right to turn out students on requirements far below these demands which are pretty uniformly the very minimum that the conditions warrant.

The report of the committee scarcely needs any elaborate explanation, but it may be well to point to some things in connection with the several sections.

First, it will be noted that in Section 1 very liberal allowance is made as to what sort of credentials a student may present; they may be from a four years' high school, from a normal school, a certificate of admission to a university or college, or by examination. It is true that the institutions from which credits may be accepted are confined to those recognized by a state university. Surely one could hardly ask a more liberal proposition than this, however; some restriction must be imposed, as it is well known that the term "high school" may mean anything from less than a good grammar school to the high grade institutions of our larger cities, and similarly the term college must be defined, for as indiscriminately used in this country it may mean anything from a cheap grade business college to an institution of real university rank.

It has been suggested, however, that in some states there is no state university and in some others the state institution does not represent the highest standards. This objection seems to your committee a valid one, and we desire to propose an amendment to the article as printed. May I say, at this point, that the committee is not at all insistent in reference to the minor details of this report; indeed, we believe that certain other changes will meet objections which have been raised by members of the Association with whom the committee have conferred, and we propose, therefore, some other amendments, presently to be mentioned. The committee is strenuous only in its insistence on the fundamental requirement of a four-year high-school diploma or its equivalent. In reference to this clause, your committee propose the following amendment: "It is moved to amend Section 1 by striking out subsections A and B, as they appear in the printed report, and substituting therefor the following: '(A) A diploma from a four-year high school, or academy, or normal school, which requires for admission evidence of the completion of an eight-year course in the primary or intermediate schools.'"

It has been objected further to Section 1, (C) that because of the great lack of uniformity among colleges, it would be difficult, if not impossible, to make sure that the certificate of admission to the freshman class of a college or university is the full equivalent of a four-year high school education. It is proposed to amend this section by substituting the following: "(C) a bachelor's degree from an approved college or university."

In specifying the subjects which may be presented on examination, it has been the aim of your committee to make the terms very liberal; no branches are made compulsory which are not already included in the demands of this Association and the additional credits which may be presented to make up the equivalent of a four years' high school course cover every branch which is at all likely to be included in the high school curriculum. It is thought by some that a larger list than this and greater liberality should be provided for in these branches of choice, and, therefore, the following amendment is proposed: Moved to amend Section 1 (D) of Article III, by adding to the branches of choice, "general history, one or more years; Greek, one or more years; logic, one or more years; psychology, one or more years; Greek and Roman history, one or more years.

Section 2 is simply an explanation of the actions of this Association taken at Saratoga last year. Some objection has been made to allowing the faculty of a literary or scientific institution to conduct this examination, while the members of the medical faculty are prohibited from so doing. Your committee propose, therefore, the amendment of Section II so that it shall read as follows: "This examination must be conducted by or under the authority of the superintendent of public instruction of the city or state in which the college is located. In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission."

Section 3 is also a simple statement of the conditions to which the Association is already committed by its action at Saratoga; the existing custom of allowing a student to enter a medical school with unlimited conditions is so illogical and indefensible that comment on Section 3 seems superfluous.

Section 5 prescribes the minimum of time attendance which is possible under existing statutes; the length of session which is laid down by our present constitution, namely, six months, is one month short of that demanded by several state examining boards at the present time.

Section 6 is modified from the existing regulations only in omitting the allowance of credit to graduates in pharmacy, dentistry, and veterinary medicine. At least four boards of health, namely, New York, Pennsylvania, Illinois and Minnesota, have already ruled in accordance with the proposed amendment. We believe that the time has come when no allowance should be given for work which corresponds so imperfectly to that of the medical schools proper. The allowance of credit for work actually accomplished in a standard university or college in the course for the bachelor's degree is retained, for it is believed by a majority of your committee that this plan has been of immense service in encouraging young men intending to study medicine to take a college course as a precedent thereto. To the argument that there are many colleges and universities whose work is unworthy of credit, the reply is obvious that discrimination must be exercised by the medical schools in this regard just as in accepting credit from other medical schools, and it is believed that there is no larger proportion of unworthy institutions of general learning than there is of unworthy medical schools in this country. Many of our better colleges now offer to students courses in chemistry, physics, anatomy (even including human dissection), histology, embryology, physiology, and bacteriology which are uniformly of higher character and will average to be much more thorough than the corresponding courses offered in the medical schools. The plan of giving a flat year's credit for a degree irrespective of work done is not satisfactory and your committee would propose that another year the amendment be modified so as to give credit only on the basis of work actually accomplished which corresponds to the work of the medical curriculum; such credit should carry with it, however, a corresponding time credit. It was thought that it would be best, however, to leave the ruling in regard to college graduates as it stands for another year.

In conclusion, we beg to express the opinion that if this report errs it is on the side of leniency because the proposed amendments will not place this Association on any higher plane, so far as requirements for admission are concerned, than has already been established by statutory enactment or the rulings of medical examining boards in several states, but the effort to make any increase in requirements has been so barren of results up to date that it was thought best not to ask more than is prescribed. We beg to express the hope that the Association will place itself again in a position which will command the respect of all those who are interested in higher medical education by the passage of the proposed amendment. By nothing less than this can the Association justify its continued existence as an organization which was established and presumptively continues to exist to elevate the standards of medical education in America.

[Signed.] Parks Ritchie.
John M. Dodson.

The following amendment was introduced by a majority of the special committee appointed for the purpose of revising Article III of the Constitution:

It is moved to amend Article III by striking out all of it and inserting in lieu thereof the following:

Article III.

Section 1. Every college holding membership in this Association shall demand of each student, as a minimum requirement for admission to the medical course, either (*a*) a diploma from a four-year high school or academy whose credits are accepted by a state university, or (*b*) the diploma of a state normal school having a course of instruction equivalent to a four-year high school course whose credits are accepted by a state university, or (*c*) a certificate of admission to the freshmen class of a state university or of a college whose credits are fully recognized by a state university, or (*d*) an examination in the following branches:

(*A*). English—grammar, rhetoric and composition, the equivalent of two years' high school work in this branch.

(*B*). Algebra—to quadratics.

(*C*). Latin—one year high school work, including grammar and four books of Cæsar, or a full equivalent therefor.

(*D*). Physics—one year of high school work, including some laboratory work.

(*E*). U. S. History—one year of high school work.

Besides the above, seven additional branches of the student's choice selected from the following:

1. Latin—one year; Cæsar, Cicero or Virgil.
2. German—one year; grammar and literature.
3. French—one year; grammar and literature.
4. Chemistry—one year; with laboratory work.
5. Botany—one year.
6. Zoology—one year.
7. Geometry—one year; plane.
8. Geometry—one year; solid.
9. Trigonometry—one year.
10. Astronomy—one year.
11. Physiology—one year.
12. Physical geography—one year.
13. English literature—one year.
14. Advanced algebra—one year.
15. Civics—one year.
16. General history—one year.

Sec. 2. This examination must be conducted by members of the faculty of a literary or scientific college, or by a superintendent of public instruction; in no case shall it be conducted by any person connected with the faculty of a medical school to which the student is seeking admission.

Sec. 3. A student may be allowed to enter on his medical work conditioned in not more than two branches (one year's work in each), but these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

Sec. 4. Colleges members of this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course.

Sec. 5. Candidates for the degree of doctor of medicine shall have attended four years' courses of study, each annual course to have been of not less than seven months' duration and at least twelve months shall intervene between the beginning of any course and the beginning of the preceding course.

Sec. 6. Time credits may be given to students who have the necessary entrance requirements and who are graduates or students of colleges of homeopathic or eclectic medicine for such courses of instruction of the required duration as they have successfully fulfilled, excepting in the course of the fourth year, provided they pass satisfactory examinations in materia medica and therapeutics. Credit for one year of time may be given to students holding the degree of A.B., B.S., or other equivalent, from a reputable university or literary college.

Sec. 7. A college which gives less than a four years' course of study, but does not graduate students and is possessed of other required qualifications, may be admitted to membership.

Note.—One year's work in any subject of a high school or academic course is defined to mean a series of daily recitations, of forty-five minutes or more in time, for each week of a school year of not less than thirty-six weeks.

This amendment is seconded by the following colleges: medical department of the University of Buffalo, Johns Hopkins University Medical School, medical department of Western Reserve University, medical department of the University of Michigan, Rush Medical College, in affiliation with the University of Chicago, Northwestern University Medical School, medical department of the University of Minnesota, medical department of the University of Iowa, medical department of the University of Kansas, medical department of the University of California.

In the form finally adopted the amendment read as follows, and it was provided that it take effect July 1, 1905:

Article III.

Section 1. Every college holding membership in this Association shall demand of each student, as a minimum requirement for admission to the medical course, either (*a*) a diploma from a four-year high school or academy or normal school requiring for admission evidence of the completion of an eight-year course in primary and intermediate schools, or (*b*) a bachelor's degree from an approved college or university, or (*c*) an examination in the following branches:

(*A*). English—grammar, rhetoric and composition, the equivalent of two years' high school work in this branch.

(*B*). Algebra—to quadratics.

(*C*). Latin—one year high school work, including grammar and four books of Cæsar, or a full equivalent therefor.

(*D*). Physics—one year of high school work, including some laboratory work.
(*E*). U. S. History—one year of high school work.
Besides the above seven additional branches of the student's choice selected from the following, each to have been pursued one or more years:

1. Latin—Cæsar, Cicero or Virgil.
2. German — grammar and literature.
3. French — grammar and literature.
4. Chemistry—with laboratory work.
5. Botany.
6. Zoology.
7. Geometry—plane.
8. Geometry—solid.
9. Trigonometry.
10. Astronomy.
11. Physiology.
12. Physical geography.
13. English literature.
14. Advanced algebra.
15. Civics.
16. General history.
17. Greek.
18. Logic.
19. Psychology.
20. Ethics.
21. Greek and Roman history.

SEC. 2. This examination must be conducted by or under the authority of the superintendent of public instruction of the city or state in which the college is located; in no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

SEC. 3. A student may be allowed to enter on his medical work conditioned in not more than two branches (one year's work in each), but these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

SEC. 4. Colleges of this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course.

SEC. 5. Candidates for the degree of doctor of medicine shall have attended four years' courses of study each, and at least twelve months shall intervene between the beginning of any course and the beginning of the preceding course.

SEC. 6. Time credits may be given to students who have the necessary entrance requirements and who are graduates or students of colleges of homeopathic or eclectic medicine for such courses of instruction of the required duration as they have successfully fulfilled, excepting in the course of the fourth year, provided they pass satisfactory examinations in materia medica and therapeutics. Credit may be given to the holder of a bachelor's degree from a reputable college or university for any work in the medical branches which he has successfully completed in his college course that is the full equivalent of corresponding work in the medical curriculum. Such a student may be allowed to complete the course for the medical degree in not less than thirty-one months, provided that he completes the remainder of the medical curriculum in that time.

SEC. 7. A college which gives less than a four years' course of study, but does not graduate students and is possessed of other required qualifications, may be admitted to membership.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the disease seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Intolerance of Milk.

Robin, in *Jour. des. Pract.*, states that milk, in order to overcome intolerance, should be given at regular intervals and in definite quantities. It is best administered hot, but not boiled. The patient should be instructed to sip it slowly and should lie quietly for half an hour after taking it, with hot fomentations over the gastric region. Diarrhea, pain, flatulence and constipation may render it difficult to keep the patient on a milk diet.

To relieve the epigastric pain and distress the following is recommended:

℞. Sodii bicarb.
Magnesiæ ustæ, āā ..... ʒi 4
Cretæ preparatæ ..... ʒiss 6
M. Ft. chart. No. x. Sig.: One to be given after each feeding of milk; or:
℞. Pil. pancreatin ..... gr. i-ii |06-.12
Sig.: One to be taken after food.

To relieve the flatulence which is dependent on fermentation the following solution is recommended:

℞. Ammon. fluorid. ..... gr. iii |20
Aq. destil. q. s. ad ..... ʒx 300
M. Sig.: One teaspoonful after taking the milk.

If in doubt as to the nature of the fermentation the following should be given:

℞. Sulphuris ..... gr. iii |20
M. Ft. cachet No. i. Sig.: One after each feeding.

To correct the constipation the following pill:

℞. Pulv. aloes ..... gr. i |06
Ext. hyoscyami
Ext. belladonnæ, āā ..... gr. 1/12 |005
Ext. glycyrrhizæ ..... gr. iss |09
M. Sig.: One to three such pills at bedtime.

The diarrhea may be checked by administering an infusion of strawberry root, using about twenty grains of the root at one dose, from which the infusion should be made, or by bismuth in proper doses.

Gastrointestinal Atony.

The following is recommended by *Médecine Orientale* in the treatment of gastrointestinal atony:

℞. Magnesiæ ustæ
Cretæ preparatæ, āā ..... ʒi 30
Pulv. calumbæ ..... gr. xxx 2
Pulv. vanillæ ..... gr. xv 1
M. Sig.: One half teaspoonful before each meal.

Chronic Articular Rheumatism.

E. C. Hill, in *Med. Standard*, recommends the following treatment for chronic articular rheumatism:

As a liniment.

℞. Linimenti terebinthinæ
Tinct. opii, āā ..... ʒi 30
Linimenti saponis ..... ʒiii 90
M. Ft. linimentum. Sig.: To be applied externally to the affected joints.

Internally the following:

℞. Potassii iodidi ..... gr. xx 1|30
Vini colchici rad. ..... m. v |30
Syr. sarsap. co. q. s. ..... ʒi 4
M. Sig.: At one dose, to be repeated after each meal; or:
℞. Liq. potassii arsenitis ..... m. v |30
Pot. iodidi ..... gr. v |30
Syr. simp. q. s. ad ..... ʒi 4
M. Sig.: To be taken at one dose and repeated after each meal.

In the aged and debilitated the following:

℞. Quin. sulph. ..... gr. iss |09
Tinct. ferri chloridi ..... m. xii |75
Elix. cascaræ sagradæ q. s. ad ..... ʒi 4
M. Sig.: One dessertspoonful three or four times a day well diluted in water; or:
℞. Potassii iodidi ..... gr. x-xx |65-1.30
Spts. chloroformi ..... m. v |30
Tinct. cinchonæ co. q. s. ..... ʒi 4
M. Sig.: At one dose, to be repeated three times a day, well diluted in water; or:
℞. Acidi salicylici ..... gr. xv 1
Elix. cascaræ sagradæ ..... ʒiv 15
M. Sig.: At one dose.

As an ointment the following:

℞. Acidi salicylici ..... ʒv 20
Alcoholis ..... ʒiii 90
Olei ricini ..... ʒvi 180
M. Ft. unguentum. Sig.: Apply locally.

Enuresis.

The following formulæ by Sheffield are recommended in the treatment of enuresis:

℞. Ext. ergotæ flu. ..... ʒiii 12
Ext. rhois toxicodendron. flu. ..... ʒi 4
M. Sig.: Five to ten drops every four to six hours.

In cases of incontinence due to hyperesthesia of the neck of the bladder, irritating foods should be avoided, sitz baths employed and the following antispasmodic mixture given:

℞. Ext. hyoscyami ..... ʒss 2
Sodii bromidi ..... ʒi 4
Aq. anise ..... ʒi 30
Syr. simp. q. s. ad ..... ʒii 60
M. Sig.: One teaspoonful every 4 to 6 hours. Counter-irritation by means of mustard plasters should be employed over the lumbo-sacral region.

Treatment of Scalp Wounds.

Bayard Holmes, in *Denver Med. Times*, gives the following suggestions in the treatment of scalp wounds:

1. Shave three inches about every scalp wound.
2. Make every scalp wound a large incised scalp wound, so that it may be explored with the finger.
3. Use no probe except the index finger.
4. Trim with the scissors the edges of the scalp wound; the razor and the brush are not effective.
5. Scrape out an old wound with a sharp spoon as a part of the mechanical removal of infection.
6. Sew up clean and bloodless scalp wounds without drainage, inserting the stitches half an inch or more from the edges of the wound and tying on one side.
7. Remove the stitches at the end of forty-eight hours, being careful to cut the stitches near the skin so that none of the exposed and infected silk will be drawn through the scalp.

Trachoma.

The following treatment of trachoma is recommended by *Médecine Orientale:* An instillation of iodic acid (1 to 100) and the conjunctiva swabbed with the following solution:

℞.	Potassii iodidi	ʒiss	6
	Acidi iodici	gr. lxxv	5
	Aquæ	ʒiii	90

M. Sig.: Apply locally. Any granulations present should be touched with a stick of iodic acid, and the membrane massaged after applying the following powder:

℞.	Acidi iodici	gr. xv	1
	Sodii iodati	gr. lxxv	5
	Acidi borici	ʒiii	90

M. Sig.: Apply locally to the affected membrane.

Pertussis.

The following outline of treatment, according to an abstract in *Month. Cyc. of Med.*, is the most satisfactory in the treatment of whooping cough: Antisepsis of the buccal and nasal mucous membrane; painting the pharynx several times a day with validol containing some oil of bitter almonds, and a 5 per cent. solution of cocain; inhalation of oxygen saturated with validol and cherry laurel water, several liters, five or six times a day; a daily change of bedroom and daily fumigation of the vacant room with sulphur; internally euquinin and belladonna:

[Validol contains 30 per cent. menthol, 70 per cent. valerianic acid, and is a nerve sedative, given internally in 10 to 20 drop doses.]

Kilmer, in *N. Y. Med. Jour.*, recommends inhalations of pure steam or creasote vapor to allay the paroxysm. This may be administered by means of the croup kettle and repeated two or three times daily. Where there is marked spasm of the glottis, inhalations of chloroform are of benefit. Antipyrin, sodium bromid and quinin are the drugs preferred by the author. For a child two years of age the following combination:

℞.	Sodii bromidi	gr. iii	20
	Antipyrini	gr. i	06
	Syr. ipecac.	m. iv	25
	Aquæ q. s. ad	ʒi	4

M. Sig.: One such dose every two hours for three or four days.

The patient is then given three grains of quinin sulphate every three or four hours for four days and then put back on the liquid combination.

He advises, as a mechanical measure, the use of a stockinet band similar to that employed by the orthopedic surgeon before applying a plaster-of-paris bandage. This band is made to extend from the axillæ to the pubes and fits the body snugly. This bandage is used to control the vomiting, and thus in nurslings prevents the inanition which would otherwise occur on account of the vomiting.

This band, it is stated, will also aid in aborting the paroxysmal stage as it is manifest that the paroxysms are very much milder when the band is worn. There is some liability, unless care is observed, to an eczema which soon disappears when the band is taken off.

Medicolegal.

Unnecessary Operation to Produce Sterility Warranting Refusal to Marry.—One of the defenses to the breach of promise case of Edmonds vs. Hughes was that at the time the party sued promised to marry the party suing the latter was a woman in possession of the power of procreation, and was able to bear children; that after the promise was made she voluntarily submitted to and permitted an unnecessary surgical operation to be performed upon her body, by which she was rendered unable to procreate or bear children, and would forever remain so. If this was true, the Court of Appeals of Kentucky holds that it constituted a valid bar to the woman's alleged cause of action for breach of promise to marry her.

Demonstration of Injuries to Jury by Expert Witness.—The Court of Appeals at St. Louis, Mo., says that, in the personal injury case of Rice vs. the Wabash Railroad Company, the company was loud and vehement in its complaint against what was termed the anatomical and surgical lecture of the suing party's expert witness in describing and illustrating, by reference to that party's nose, the nature of the injuries sustained. But, if the method adopted by the party suing in presenting such testimony was effective and potent, the court says, the presiding judge was clothed with broad discretionary authority in the proper course and seemly conduct of trials before him, and, in the absence of clear abuse of such power, the court is inclined to defer to his action, and assume that he properly controlled the management of the trial, and it is not disposed to hold that the manner in which the injuries of the party suing were demonstrated by the physician to the jury constituted reversible error.

Bases of Non-Liability for Negligence of Physicians.—The Court of Appeals at St. Louis, Mo., says, in the malpractice case of Haggerty vs. the St. Louis, Keokuk & Northwestern Railroad Company, that the later judgments have apparently renounced the notion that whatever immunity from the law of respondeat superior (the superior or master must answer) is enjoyed by eleemonsynary trustees and corporation is allowed in order to protect trust funds and public money from outlays not contemplated by the donor or the legislature. Recent cases which exonerate charitable institutions from liability for certain negligent acts of employes, such as unskillful treatment or nursing, appear to do so on the theory that a patient, in accepting gratuitious attention of that kind, assumes the risk of injury by the carelessness of employes. But it was obvious, the court says, that neither the railroad company sued nor its relief department was the trustee of public funds put into its hands to use in a prescribed manner. Nor, in view of the regulations provided for its government, could the relief department be classed as a charity without doing violence to every significance that word bears, either in popular or legal usage. The fund administered was not a gift by the employes, who made contributions; much less by the railroad company, which did not make any unless a deficit occurred. The fund was made up from sums contributed by the members for their mutual benefit, and to be enjoyed by them if they suffered from sickness or accident. It was, in effect, a provision made by the employes to insure a stipend for them to live if they were disabled, and a benefit to their families if they died. In addition to this, if disabled by accident, their medical attendance was paid out of the fund. This strikes the court as a purely business arrangement on the part of the employes of the railroad company. To call the enterprise a charity on the part of the company itself is extravagance, when it is noted that one of its purposes, as carved in high relief on the face of the regulations, is to prevent damage suits. Enterprises much more benevolent have been excluded from the list of charities by the courts. To give such organizations as this one the legal status of a charity, and determine the employer's liability on that theory, is not only illogical, but must ultimately prove pernicious, by subverting to commercial and selfish uses principles of law designed to protect only benevolent institutions. Wherefore the court declines to accede to the argument that the party

suing here for malpractice had no case, because, if treated by the company's physicians, he was the recipient of charity. Unquestionably, if it undertook to supply him with surgical attendance, or deprived him of a choice in the matter, it was bound to employ reasonable care to get men of average skill. But its obligation ended there, though not on the principle that it was operating a charity. In cases like this the surgeon is not regarded as sustaining in full measure the relation of servant to the railway company, which carries the right of direction and control as to the mode of doing the work. There is little likelihood of railway companies or other employers becoming careless in the selection of physicians to wait on employes; and, as their business managers and superintendents are not selected for their expert knowledge of medical and surgical matters, they are unfit to supervise the work of physicians, and therefore the doctrine of respondeat superior, or that masters are answerable for the wrongful acts of servants, cannot well be applied to such matters. These, the court thinks, are the real reasons why the courts have refused to extend the rule to them.

Requisites to Charging Wife for Medical Services.—The Appellate Term of the Supreme Court of New York says that the sole question in the case of Hazard vs. Potts was whether the wife there sued was liable for medical services which it was admitted were rendered to her husband and his family. The court says that the liability for such services was presumptively and primarily on the husband, unless the wife, by express agreement, charged herself personally with the same. Therefore, in order to charge her with liability, it was necessary to prove that she undertook liability, and that such services were rendered on her credit. The evidence showed that the services were rendered on the request of different members of her family; but, even if she had requested the rendition of any of them, such request, the court holds, would not have raised any implied promise on her part to pay for the same; but, on the contrary, since all the services were necessary for her family, and the physicians knew it, the presumption would be that she had made such request as agent of her husband. The record was barren of any evidence tending to show that the services were rendered upon her personal credit, or that the physicians, when they rendered them, told her that they would look to her for payment of the same. Under these circumstances, no recovery against her could be maintained, unless some effect could be given to testimony adduced that, after all the services had been rendered, she made two payments on account, and thereafter asked for a bill, and said she would probably pay the claim in installments; subsequently she wrote one of the physicians that as soon as she was able to go to New York she would call, and that she meant by that letter that she wanted to go there for the purpose of borrowing money from a friend; thereafter, one of the physicians and his brother called at her residence, where they at first met her husband, who excused himself by saying that his wife would be in presently and talk with them, and that she then appeared and stated that they wanted to pay the bill if given time to do so, and that she was willing to give a note, but that she could not speak for her husband, and that a day or two thereafter she told a lady that she would pay the bill. The wife, however, denied that she promised to pay such bill, but, even if she did, the court holds, such promise would not, for obvious reasons, enable an action to be maintained thereon, but might, at most, be some evidence of an agreement at the outset to pay, if nothing appeared to the contrary. Such question, however, need not be considered, since it appeared from the evidence that the physicians did not have any conversation with her about payment for the services until after they had been rendered. There was therefore no evidence in the case from which it might be legitimately inferred that the services were rendered upon the agreement of the wife to be personally liable for them. On the contrary, the bills rendered by the physicians were made out to the husband, which facts strongly tended to show that the services were rendered upon his credit alone. Hence, in the absence of an original agreement to be personally liable, the wife's alleged subsequent promise to pay for them, even if established, must be presumed to have been made in her relation of wife, and in the exercise of her implied agency to obtain medical attendance for the family. Wherefore, in the absence of proof showing an agreement on her part to be personally liable, the court holds that a recovery against her was not warranted.

1. **Uterine Myoma.**—Hunner's article is an analysis of 100 cases, including 31 colored and 69 white women. The admissions of colored women are only about one-sixth of the total, showing that myoma is nearly twice as frequent in the colored as in the white race. The youngest patient was 24, the oldest, 67. The majority were in the fourth and fifth decades of life. He remarks in regard to the caution required to distinguish between fibroid and pregnancy. Of the chief symptoms, 35 patients complained of abdominal tumor. In 2 cases this was the only symptom. Pain in the abdomen, pelvis or diaphragm was complained of by 53 patients. An increased menstrual flow was noted in 41 cases. Copious hemorrhages at or between the menstrual periods occurred in 15 patients, making 56 per cent. with hemorrhagic loss of blood. In 9 cases the hemoglobin at time of operation was 46 per cent. or lower. These all recovered in spite of the anemia. In the older patients hemorrhage was a prominent symptom in the majority and in only the minority of these cases was it of the menstrual type. One patient had undergone a double oöphorectomy eleven years before, with only temporary relief. Gastric symptoms were prominent in 6 cases. A number of patients suffered from complications. Carcinoma of the fundus was present in 3, of the cervix in 2 cases and sarcoma was present in 2, making 7 per cent. of malignant disease. Adenomyoma was present in 2 cases. Many cases exhibited complications outside the uterus and tumor involving the uterine adnexa. Six patients died, as against only 2 per cent. in ordinary gynecologic operations. In 5 of these there was serious pelvic inflammatory disease and complications. The operations performed were myomectomy in 19; panhysteromyomectomy in 14; supravaginal hystero-salpingo-oöphoromyomectomy in 40 cases, and supravaginal hysteromyomectomy, leaving one or both ovaries, in 16; vaginal myomectomy in 5 cases, and vaginal hysteromyomectomy in 6. Nine patients were treated by the method of bisection. He thinks if we can find in a series of 100 cases such a record of suffering, sterility, miscarriage, etc., one will not wonder that he announces his attitude toward myoma of the uterus as radical.

2.—This article appeared elsewhere. See THE JOURNAL, xl, title 155, p. 1263.

3. **Nasal Sinusitis.**—The diagnosis of inflammatory conditions of the frontal, antral, ethmoidal and sphenoidal sinuses is discussed at length by Freeman, who thinks that the transillumination test has been too much relied on. Frontal sinusitis is generally easily diagnosed, though there are conditions in the absence of pain, usual with free drainage, where our attention may not be directed to the proper locality of the suppuration. In antrum inflammation no sign has been as useful to him as the discovery of pus flowing over the upper surface of the posterior end of the inferior turbinal. He has also been able to make a tentative diagnosis of sinusitis by

certain well-defined odors, those of sour pus and of sulphuretted hydrogen. The symptom of intermittent cacosmia is very significant of sinus suppuration, generally of the antrum. Syphilitic necrosis in the sinus, however, may be an exception. The presence of discolored molars or bicuspids is always significant and suspicious. A capped six-year molar is always suspicious. Any tooth from the wisdom to the central incisors may be the cause of antrum inflammation. In endeavoring to wash out the antrum through the normal opening, he has found it of advantage to explore first with a delicate cotton wound-probe, the point curved downward, and he has also devised an irrigation cannula which has proven of great service to him. It is made of hard rubber and easily molded to any shape by heating and is not so uncomfortable as a metal tube. He thinks the ethmoid is not infrequently credited with trouble which is due to the antrum, and before sacrificing the middle turbinal it is due the patient to at least suspect the antrum and try irrigation. Except in atrophic rhinitis or in rare cases of deformity of the septum with accompanying lack of development of the turbinals, a direct flow of pus from the sphenoid opening can seldom be seen. Edema of the mucous membrane at the upper portion of the septum posteriorly should direct our attention to the sphenoid. The statement that the formation of crusts in the vault warrants a probable diagnosis of sphenoid disease, as asserted by Schaeffer and others, is, he thinks, misleading. Vertigo and pain at the occiput, deep in the eyes and in the ears, may be caused by disease of any one of the sinuses, and the distressing pain across the bridge of the nose considered so characteristic of ethmoid disease is repeatedly caused by manipulations within the sphenoidal cavity. In regard to ocular manifestations, he quotes Posey, who says that the general symptoms of asthenopia, which are obstinate and not relieved by glasses, should direct attention to the nasal sinuses. Freeman advises against the use of suprarenal extract in examination for sinus suppuration, as the blanching of the surfaces prevents the recognition of small amounts of secretion. He has found it useful to have the patient close the opposite nostril and sniff and blow alternately. This draws the pus rapidly from the sinuses and saves time. The morning is the best time for detecting pus from the frontal and ethmoids and the evening for secretion from the antrum and sphenoid.

14 *Radiotherapy in Enteritis and Colitis. Sinclair Tousey.
15 *Some Observations on Stacke's Operation. Thomas R. Pooley.

8. **Shoulder Dislocation.**—Beck reports a case where, on account of a recurrent humeroacromial dislocation of the shoulder, he operated by exposing the acromial surface of the capsule, which was found to be so much relaxed that a fold could be taken up and contracted by making a purse-string suture in it. At the same time a hole was drilled into the head of the humerus and into the acromion and a medium silver wire carried through it to ensure retention of the head by adhesion formation. There was no evidence of rupture of the supraspinatus muscles, or, infraspinatus, causing rupture of the capsule or any abnormality of the joint. The operation was followed by no reaction and when the wire was removed five weeks later the result was good. Six months after operation it appears perfect.

10. **Intravascular Antisepsis.**—Barrows continues his article on the formaldehyd treatment of septicemia and mentions its advantages. He quotes, in conclusion, from Sajous, that it has an effect in stimulating the adrenal system if used in moderate doses.

12. **Typhoid Fever.**—Davidson has studied a number of cases of typhoid occurring in his practice and finds in every instance evidence of a water-borne infection. He does not pretend to say that infected fruit and vegetables might not sometimes be responsible; they may lie on the ground and come in contact with infected water from some source or other, but so far as his observations go, he has not been able to trace a single case to anything except an infected well.

14. **Radiotherapy in Colitis.**—Tousey has begun the use of electrotherapy in certain cases where there is a chronic condition of pain or discomfort with frequent mucous and occasionally bloody discharges and false membranes, and which have failed to yield to the use of intestinal antiseptics. The way he made the applications has been by having the patient lie flat upon an examining table with the surface of the abdomen exposed, and with an *x*-ray tube supported eight inches from the surface, with the rays directed principally to the painful part. At this distance the exposure may last for three to five minutes for the first treatment and may be gradually increased in duration. He takes precaution to use a large tube, 40 cm., and to avoid allowing the platinum disc to become red hot. To avoid this it is necessary to turn off the current several times during a long exposure. We must consider the character of the parts exposed to the light, the degree of vacuum in the tube as well as the duration and frequency of the applications. The parts which it is not desired to influence should always be protected by sheet-lead or something else opaque to the *x*-ray. In addition to the *x*-ray proper he has made other applications by means of glass vacuum tubes connected by a thoroughly insulated wire with one pole of the great Ruhmkorff coil, which should form part of the *x*-ray outfit. When the current is turned on such a tube is filled with a wave of light passing from the rheophore toward the bulbous extremity, which is in contact with the skin, and the patient receives, with hardly any sensation, a wave-like discharge of very high voltage and considerable amperage. The connection is with only one tube of the coil. The tube is provided with an insular handle for the use of the operator. If removed from the skin a shower of sparks passes from the vacuum tube and does not seem to produce as good results as the direct contact, and is more disagreeable. Direct application is almost without sensation, but the patient can give another person quite a spark by touching him. He has had his patient, more or less, completely insulated, but is not certain as to the importance of this point. The cases under treatment seem to show an improvement, perhaps on account of the novelty, as the author suggests, but his expectation of lasting benefit is not so much on account of the germicidal action of the *x*-ray as on account of the stimulating and altering effect of the combined application of the *x*-ray and the high tension discharge from the vacuum tube.

15. **Stacke's Operation.**—The radical mastoid operation generally known as Stacke's is criticised by Pooley, who points out the following dangers of the procedure:

1. The wounding of the facial nerve, dura, lateral sinus and the semicircular canals.

(*a*) The facial nerve may be wounded on account of its anomalous position, carelessness in chiseling too near the floor of the external canal, or the too tight packing of the wound.

(*b*) In using the middle ear curette it must not be forgotten that the tympanic walls are often very thin from necrosis and the internal carotid artery, as well as internal jugular vein, are imperfectly protected and liable to be penetrated.

(*c*) In carrying the operative procedure upward and backward the semicircular canals must be avoided.

2. In contemplating this operation it must be taken into account that a radical cure is by no means always obtained by one operation. A second operation, or even a third or fourth, may be necessary, in order to obtain a complete cure of the otorrhea.

3. The length of time required for the healing process may vary from three to six months. And lastly,

4. The possibility of permanent impairment of hearing in patients who, before the operation, could hear fairly well.

Considering these and the uncertainty of cure, together with the long duration of after-treatment, he thinks every case of chronic otorrhea should be carefully studied before being subjected to such severe operative procedure. While he does not wish to detract from the merits of the operation, he does not think all cases of chronic otorrhea should be indiscriminately so treated. In spite of the present opinion against the cure of otorrhea by medication, removal of polypi,

and intratympanic curetting, he holds that each of these methods often meets with success. Many cases of chronic suppuration of the middle ear can be healed by vigorous antiseptic treatment, removing granulations, cholesteatoma, etc. He summarizes his view as to when operation should be performed as follows:

The objective indications may be grouped under two forms: any case of reinfection or of a rapid extension of a chronic otitic process, or whenever a grave complication is threatened; the indication is then for immediate operation.

The indication is not immediate when the patient suffers little or no pain and there is no striking symptom in the mastoid, but even here the indication may be operative. If the osseous lesion is extensive. The subjective symptoms are: persistent and recurrent pain in the ear or mastoid process, with persistent and fixed pain in the parietal or occipital region, increased by percussion, which frequently points to temporal or cerebellar abscess; vertigo, either permanent or intermittent attacks, which may be due to erosion of the external semicircular canals, and well-marked brain symptoms, such as headache, heaviness, pressure, torpor, loss of consciousness, etc.

17 *Notes on the Selection of a Climate for the Treatment of Tuberculosis. Russell Bellamy.
18 *Hypnotism and Hysteria. Wm. B. Pritchard.
19 *Dry Superheated Air in the Treatment of Septic Infection. Clarence E. Skinner.
20 *The Sanatorium Treatment of Tuberculosis. (Concluded.) Herbert M. King.

16. Stomach Vertigo.—The various theories of stomach vertigo are reviewed by Fischer, who thinks it is unproven that there is any relation between abnormal gastric secretion and vertigo. He has taken from his own records a number of cases bearing on this point, and finds that both subacidity and acidity may exist with this symptom and not much difference in proportion from those that occur with normal gastric findings. There is very little relation between gastric acidity and vertigo in his opinion. The simplest clinical indications of gastric irritability are pain and nausea, and it would be interesting to know in what proportion of vertigo symptoms these two symptoms are pronounced. From his own observations it would seem that very little causative relation exists between gastric irritability and vertigo in inflammatory affections of the stomach, nor does he find that atony or gastroptosis seem to have very marked relations, though each may have its effect. That vertigo should be associated most frequently with atony is comprehensible, as atony is the most frequent pathologic condition in chronic gastric disease. Autointoxication is also doubted, as it can not explain all cases. He makes the classification of vertigo into: 1. Those in which it is intense and is the only prominent nervous system. 2. Those where it is associated with intense palpitation, precordial fear, dyspnea, and possibly syncope, following isolated acts of indiscretion in diet. 3. Cases where it occurred as a momentary sensation in the course of well-defined pathologic conditions in the stomach. The first class assumes the existence of a chronic gastric disease with or without dyspeptic symptoms. There are no specific gastric states with which this type can be directly connected and fortunately the cases are rare. The second type is more frequent, but can hardly be justifiably called gastric vertigo, for the latter is not the principal feature of the attacks. Many of them occur very soon after meals, thus eliminating the possibility of fermentative and putrefactive changes. The third class comprises those cases in which the vertigo is associated with chronic gastric diseases as a momentary sensation. These are numerous, but the causative relation of gastric disorder is often very obscure. There is generally an accompanying neurosis. The author is inclined to think that the vertigo is due either to external influences affecting the special senses, or originates in the central nervous system as the result of a predisposition engendered by mental depression or irritability. Fischer seems to consider that the stomach has been credited with more than is properly its due in these cases.

17. Tuberculosis.—Bellamy describes the climates of New Mexico, Colorado and Arizona, and in summing up their advantages offers the following points: 1. Consumptives with a rapid breaking down of lung tissue should avoid high altitudes, although he has heard of many cases being taken 2, those with especially developed cardiac lesions, with a marked tendency to a disturbance of cardiovascular balance. 3. Those completing the fifth decade, where the capacity of muscular exertion is considerably limited, should avoid high altitudes, although I have heard of many cases being taken to Colorado, recovering and taking up their life there. 4. Laryngeal cases do better at the low altitudes.

18. Hypnotism in Hysteria.—Pritchard advocates the utility of hypnotism, although there seem to be some contraindications such as delusional insanities and organic and toxic nervous diseases.

19. Superheated Air in Sepsis.—The good effects and mechanism of superheated air in cases of sepsis are described and illustrated with cases by Skinner. The mechanism is, according to him, through the reflex stimulation of the vasomotor tracts relieving stasis and lessening pain, augmenting the nutrition by stimulation of the trophic centers, the raising of temperature, disturbing the conditions favoring propagation of micro-organisms and stimulating the integumental emunctories to increased function. He doubts there being any danger from local hot air applications in localized infections. He has never heard a logical defense of this charge and has never heard of an authentic case where there was any satisfactory evidence that such a result was properly attributable to hot air. There is no hard and fast rule as regards the duration of application and the intensity of the heat. Overstimulation should be avoided. In non-febrile cases and those exhibiting only a low degree of febrile action, it is usually an indication that sufficient influence has been induced when the mouth temperature has been increased 2 F. above the normal or the pulse has been accelerated to 120 or 130 beats. Other measures should also be employed, such as electricity, the judicious regulation of diet and of the excretory functions, proper surgical dressing, etc. While hot air is a good thing in septic infection it is not invariably a sure thing. It will cure unaided and alone many cases. Others will require all the remedial sources at our command.

20. The Sanatorium Treatment of Tuberculosis.—King concludes his article and sums up that sanatorium treatment consists in placing the patient in the best possible environment to aid resistance and counteract the effect of waste and toxins. This is done by: 1. Securing increased sunlight; 2, enforced rest in the open air day and night; 3, increased consumption of proteids; 4, accurately governed exercise; 5, constant and unremitting medical supervision. If this can be had at home, so much the better, but he has rarely found it possible.

22 *The Physician and the Ophthalmoscope. Francis Valk.
23 *The Cystoscope; Its Indications and Contraindications in Genito-urinary Diseases. Follen Cabot and Henry G. Spooner.
24 A Case of Paraffin Injection Into the Nose Followed Immediately by Blindness from Embolism of the Central Artery of the Retina. Lee M. Hurd and Ward A. Golden.
25 Some Practical Remarks on the Management of Breech Presentations. Joseph Kucher.

22. The Ophthalmoscope.—Valk describes the methods and use of the ophthalmoscope and what it reveals, and calls attention to the importance of the physician's understanding the use of this instrument.

23. The Cystoscope.—Cabot and Spooner describes the cystoscope and its use, pointing out that the physician must learn not only how to insert the instrument, but also how to interpret the images seen. It should never be used until we have acquired an accurate knowledge of the length and caliber of the urethra and tested the capacity of the bladder. It is in bladder diseases that its principal value exists, though it may be of use as an aid in the diagnosis of diseases of the prostate gland. In case of foreign body it may aid a doubtful diagnosis. It is contraindicated in nearly all cases of acute cystitis and probably in tuberculous cystitis, though it can at least tell us the extent of the involvement, when it can be employed without too much aggravation of painful symptoms, and it alone reveals ulceration.

Boston Medical and Surgical Journal.

July 9.

26 *Subparietal Injuries of the Kidney. (To be continued.) Francis S. Watson.
27 A Case of Acute Epididymitis in an Undescended Testicle, with Gonococci Demonstrated in the Excised Organ. Fred T. Murphy.
28 The Nernst Lamp for the Production of Ether Waves for Use in Therapeutics. William Rollins.
29 A Case of Malignant Endocarditis with Meningitis, Pneumococcus Infection. L. C. Miller.

26. **Subparietal Injuries of the Kidney.**—An experience of 6 cases led Watson to investigate the subject. He has collected, formulated and analyzed clinical data from 660 cases, including all previously published series of importance and all but about 78 individual cases scattered through the literature, which are inaccessible to him at this time. Kidney lacerations may be due to muscular action alone and to apparently very inadequate force. Eleven cases of this character were found and are given in brief. In 20 cases the injury was the result of blows upon the abdomen. Where a single intraperitoneal organ was injured in association with the lacerated kidney, in all instances it was on the same side as the kidney injured. Abdominal symptoms, such as are usually associated with peritonitis, occurred in 18 cases, in 8 of which operation demonstrated the absence of any intraperitoneal complication, and in the other 10 the symptoms subsided so rapidly as to exclude such. Such symptoms are not infrequently seen in conditions which appear to be abdominal muscular contusions only. In a larger number of cases, the abdominal symptoms did represent intraperitoneal complications. Tumor in the loin appeared in 111 out of a total number of 486 uncomplicated cases, chiefly caused by hemorrhage in the peritoneal tissues. In other cases the tumor was due to traumatic hydronephrosis or perinephritic abscess. When due to perirenal extravasation it may appear almost immediately and frequently within one or two days. Subparietal injury of the kidney is rather an infrequent condition. Out of 2610 autopsies at the Middlesex Hospital in ten years there were but 12 cases. Other hospitals show similar proportions. Nevertheless it is evidently the most frequent resulting lesion in the abdominal viscera in cases of abdominal contusion, as shown by Makins' table of such cases. In a few cases it may be due to direct impaction of the ribs. In others it would seem probable that it may be due to hydraulic pressure acting through the full vessels and pelvis and causing rupture, as alleged by Küster, quoted by Morris. The regenerative power of the organ and its ability to keep up the function under such circumstances is remarked upon. The hemorrhage may occur either as hematuria, perirenal, intrarenal or intraperitoneal, the hematuria being the most common and present in at least 80 per cent. of all cases. It may last for considerable periods, even up to fifty days or more as in one case reported, but the average time is eight days according to records. Perirenal hemorrhage may be spontaneously arrested by pressure on the parts or by thrombus formation. Injury to the renal blood vessels occurred in 4 cases. Morris has collected 19 cases of aneurism of the renal vessels. Suppuration seems to be variously estimated as regards frequency. It was noted in 68 cases out of 486 uncomplicated ones. The most fatal factor, however, was hemorrhage, which was responsible for 25 deaths out of a total number of 112 uncomplicated cases which ended fatally. Laceration of the peritoneal or intraperitoneal organs is the most fatal complication, and is usually due to intraperitoneal hemorrhage. The total number of cases of this complication was 62, and the total number of deaths 48, intraperitoneal hemorrhages causing death in 36 of these 48, or a little over 66 per cent. Twenty-five of the 112 deaths of the 486 uncomplicated cases were due to suppuration. Anuria caused death in 10 of the series in which but one kidney was injured and the other normal. In several others, death resulted from laceration of both kidneys and in 4 there was only one kidney. There were 9 deaths referable to peritonitis in the uncomplicated cases, 5 of these having injuries of the abdominal organs associated with that of the kidney. As regards treatment, it would appear from analysis of the 487 uncomplicated cases that the smallest percentage was in those operated on otherwise than by nephrectomy; the percentage here was only 7. Expectant treatment gave a little better percentage than nephrectomy. (The article is to be concluded in a coming number.)

30 *Absence of Gastric Juice; Its Significance and Treatment. Henry W. Bettman.
31 Surgery of the Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

30. **Achylia Gastrica.**—This disorder, which is generally a benign one, is described by Bettman, who calls particular attention to the peculiar vomiting and characteristic emptying of the stomach after test meals. The particular type of vomiting, characteristic of achylia, as he portrays it in two typical cases, has not been described by other writers. It occurred from two to three times every twenty-four hours, fluid being ejected with marked force and without warning. The author remarks that only under certain conditions is it difficult to distinguish achylia from cancer. In the latter, pepsin can be demonstrated in the large proportion of cases, and the actual dyspeptic symptoms are very much more marked. The blood changes are characteristic, and hematemesis, tumor, belching, lactic acid and the bacteria of the gastric contents are all wanting in achylia. The chief symptom in common is progressive loss of weight. In all cases of achylia it is well to think of the possibility of cancer, though so far as he knows no case has been reported where cancer was its result. In treatment we should consider first the activity of the motor function and that intestinal digestion is usually sufficient. Treatment, therefore, consists in an intelligent effort to ignore the stomach altogether. Where gastric irritability exists, lavage is indicated, and irritating substances should be avoided in the diet. Where the symptoms are chiefly intestinal, the diet should be directed entirely to them. Bettman finds that meat is excellently tolerated. He has had cases recover completely on a diet in which meat and raw eggs predominated. Flatulence may contraindicate milk; in other cases it may be well borne. Drugs are not indicated except for special conditions.

40 Some Observations on the Treatment of Pulmonary Phthisis in Private Practice. H. J. Chapman.
41 Successful Case of Pigskin Grafting. Wm. Flegenheimer.
42 The Mineral, Animal, Vegetable and Spiritual Kingdoms of Food. Ephraim Cutter.

33. **The Gall Bladder.**—Johnson holds that the gall bladder is useless and dangerous, and that it should be removed in all cases where the biliary and common ducts are unobstructed. The most important factor in the production of gallstones is the lack of proper drainage, due to the anatomy of the parts or the presence of bacteria. Cholecystitis is the most dangerous condition for which we are called on to operate, and it is the only one in which a stone lodged in the cystic duct should be left for a secondary operation. He does not think there is any history of cases of reformation of gallstones after operation.

43 *A Method for Radical Cure of Vesico-vaginal Fistula Without Loss of Vesical Tissue. R. F. Amyx.
44 *The Healing of Granulating Surfaces by Application of Cobalt-anrate Animal Membrane. Warren B. Otten.
45 Cerebral Softening or Encephalomalacia. John Punton.
46 Extrauterine Gestation—Report of Three Cases. C. E. Ruth.

43. **Vesicovaginal Fistula.**—Amyx describes a method of treating vesicovaginal fistula by dissecting a circular flap around the fistula and inverting it and stitching it into the bladder by carrying the stitches inward through the urethra. It is useful for small fistulas. In larger openings, one-half to

one inch in diameter, he would recommend a wider dissection of the circular vaginal flap. The after-treatment consists in inserting a soft rubber catheter in the bladder for drainage, and at the end of fifteen days the interrupted silkworm-gut sutures are removed. The catgut anchor sutures attached to the pubes are absorbed on the fourth or fifth day. He thinks the operation has the advantage of no loss of vesical tissue. A portion of the vaginal mucous membrane is used to lengthen the tract so that a long invaginated tract can be obtained. The large area of freshly exposed surface is obtained for the purpose of repair in the invaginated portion.

44. **Cobalt-Aurate Membrane.**—Outten recommends the use of gold-beaters' skin put in hot sterile water, from 98 to 100 F., then inserted into a solution of cobalt and gold chlorid, 1 ounce and 1 dram respectively in, 10 ounces of distilled water, and 2 ounces of oil of cassia is added after the membranes are immersed. They turn a dark, purplish hue, showing a deposition of the chemical salts. They are kept in wide-mouthed, glass-stoppered bottles, and when used on granulating surfaces are cut out the size of the surface; after being washed in alcohol and hot water to remove the cinnamon oil, they are punctured and put over the wound, and then covered with six or eight layers of sterile gauze. Another piece of membrane is applied on top of the gauze, and above this a bandage of sterile cotton. The dressing thus applied may be allowed to remain undisturbed for at least forty-eight hours. Within twelve or fifteen hours after the application of the cobalt-aurate membrane on any granulating surface, the membrane in contact with the granulation is completely absorbed with no vestige remaining. The granulations assume a bright, vivid, healthy hue and the epithelial border appears to be stimulated in a remarkable manner. The chemical agents contained in the meshes are deposited on the surface of the granulation. As an aid in the perfect establishment of skin graft, he thinks the method is ideal.

50 Report of a Case of Traumatic Tetanus Treated with Antitetanus Serum. W. A. Kuflewski.
51 Report of a Case of Congenital Pulmonary Stenosis with a Discussion of the Case. Ellis K. Kerr.

47. **Genu Varum and Genu Valgum.**—From a study of these conditions with illustrations by skiagrams, etc., Blanchard holds that epiphysiolysis is hardly worthy of consideration as a remedy as compared with either osteotomy or osteoclasis. That osteotomy has some slight dangers from which osteoclasis is free, and the comparatively prolonged time required for bone union and recovery should condemn it when osteoclasis is available.

48. **Puerperal Sepsis.**—Fowler reports a case of puerperal sepsis treated by continuous intrauterine irrigation, and gives the advantages of the treatment. He does not think there is much danger of forcing septic fluid through the fallopian tubes with the pressure used. No case of air embolism has been reported, though other emboli have been in three cases. Hemorrhage is not serious, and while puncture of the uterus has occurred twice by the use of the hand bulb syringe, no such accident has occurred with the fountain syringe. Most of the symptoms of shock may be prevented if the irrigations are taken slowly with the cervix dilated and water at 100 F., gradually lowered as needed. He thinks all serious objections to this treatment can be overcome by the use of sterile water at a proper temperature and pressure for the case in hand.

Journal of Cutaneous Diseases, New York.

July.

52 A Case of Chronic Purpuric Erythema (Eight Years' Duration) with Pigmentation of Skin and Enlargement of Liver and Spleen. William Osler.
53 *"White-spot Disease." James C. Johnston and Samuel Sherwell.
54 *Sarcomatosis Cutis. Grover W. Wende.
55 *Parapsoriasis. L. Brocq.

53. **White-Spot Disease.**—Johnston and Sherwell report a case of this condition, which they find to be a pure degeneration of the skin, limited to the papillary body and the upper portion of the reticular layer. The whiteness is probably due to the translucency of degenerated skin, which is opaque in the reflected light. The disease should be classed with the atrophies, next to symmetrical atrophy, which perhaps closely approaches it. The name "white-spot disease," which Westberg gave it in 1901, is characteristic enough to be retained. The spots are arranged like beads on the chest, very slightly raised above the surface and smooth. The color is the dead white of snow. In the course of time some of these undergo involution and scaly separation. There is left an atrophic area exactly corresponding to the spot which preceded it.

54. **Sarcomatosis Cutis.**—Wende's conclusions are given as follows:

1. Sarcomatosis cutis (Kaposi), which is now designated as sarcoid growths of the skin, is clinically recognized as having its own individual characteristics. 2. It chiefly attacks adults. The initial lesions are small papules deeply seated in the skin. These gradually develop to a certain size, when some break down, suppurate and end in exuberant granulations. 3. Histologically it consists of a round-cell infiltration primarily existing in the deeper layers of the skin, around the blood vessels, hair follicles, sebaceous glands and lymphatic spaces. While this is suggestive of true sarcoma, it may present the inception of granuloma. The etiology is at present obscure; apparently we have to do with an infectious disease. 4. While there is a strong resemblance microscopically to mycosis fungoides, the clinical appearance is so entirely different that one need not hesitate to exclude that affection from consideration, it being separate and distinct from this. The theory of syphilis is contraindicated by the clinical appearance and therapeutic test. Lymphoderma and blastomycetic dermatitis are excluded by the microscopical findings. Carcinomatosis cutis is also ruled out by the microscope, although the clinical appearances in the two are very similar. 5. Taking into consideration the spontaneous disappearance of the tumors; the limitations of the growths to the skin without any remarkable tendency to infiltration of the surrounding tissue: the non-involvement of lymph nodes or metastasis, and the fact that the malady remains a cutaneous disease, the conclusion is forced on us that the present case far more closely resembles granuloma than true neoplasm.

55. **Parapsoriasis.**—This name is given by Brocq to a type of dermatoses first described by him as *erythrodermies pityriasiques en plaques disseminées*, which he subsequently included under the term parapsoriasis. He gives the history of the affections. They have certain features in common. Histologically this group is characterized by an infiltration of round cells about the dilated papillary vessels, flattening of the papillæ and a marked tendency to their disappearance; by a marked edema of the upper layers of the derma, and of the epidermis; by almost complete disappearance of the germinative layer; by a dilatation of the intracellular spaces in the prickle layer; by an edema of the granular layer, which is wanting in places; by the absence of the stratum lucidum, and by the absence of nuclei in the horny layer, except over the places where the germinative layer is absent. The lesions are characterized by their long duration; the slowness of their evolution; their torpidity; the slight disturbance of the general health; absence of itching, and the superficiality of the process. They are very resistant to all local medication. He describes the three following subdivisions: 1. A variety closely related to psoriasis, parapsoriasis guttata; 2, one intermediate between lichen and psoriasis, psoriasis lichenoides, and 3, parapsoriasis in patches, closely allied to seborrhea psoriasiformis. The etiology and pathology of these are obscure. They seem neither contagious nor epidemic. They may appear at any age, in any class, and are slightly more frequent in women than in men and in youths and adults. To cause them to disappear he has seen nothing to equal the cacodylate of soda, which is often inert. He has had some benefit from the glycerites locally, but the best results have been obtained through an ointment containing 10 per cent. of pyrogallic acid, to which was added 2.5 per cent. of salicylic acid. This may have to be pushed to the limit of tolerance, care being taken to avoid general intoxication, keeping the patient under close supervision.

Journal of Nervous and Mental Disease, New York.

56 *A Case of Progressively Developing Hemiplegia, Later Becoming Triplegia, Resulting from Primary Degeneration of the Pyramidal Tracts. Charles K. Mills and William G. Spiller.
57 *The Results of Surgical Treatment of Brain Tumors. M. Allen Starr.
58 *A Contribution to the Pathology of Paramyoclonus Multiplex (Friedreich's Type). J. Ramsay Hunt.

56. **Progressively Developing Hemiplegia.**—From the report of cases here studied and others from the literature, Mills and Spiller conclude that there is a form of progressively developing hemiplegia usually of the ascending type, sometimes becoming triplegia, or even quadriplegia, due to progressive primary degeneration of the pyramidal tracts, which begins on one side and may extend to the other. The clinical picture may be produced by other lesions, but they hold that they have established the fact that primary progressive degeneration of one pyramidal tract occasionally occurs, this is a unilateral lateral sclerosis. They discuss the subject of primary bilateral sclerosis, quoting cases reported by Erb as indicating that primary spastic paralysis exists.

57. **Brain Tumors.**—Starr has collected and analyzed a number of cases operated on for brain tumor, cerebral and cerebellar, making a total of 365, in 11 of which the tumor was not found, and in 27 of which it was not removed. In 59 cases the tumor was removed, but the patient died, while in 168 the patient recovered. The accuracy of diagnosis is greater in recent years, and, he says, given a history of slowly progressing disease, with symptoms of headache, vomiting, vertigo, cerebral discomfort, progressive emaciation and feebleness, and gradual loss of sight due to choked disc, the only possible hypothesis is the existence of brain tumor. The localization of tumor has become more definite and the newer surgical means of access to the brain have rendered operation safer. The invention of the electrical saw is of special advantage in the surgery. It has been shown that it is of great importance in extraction of tumor to have plenty of space, and that large bony flaps can be replaced without danger. It has also been shown that extensive cutting and taking away of parts of the brain is not necessarily attended by danger if hemorrhage is not extensive. For these reasons he thinks the statistics of the next ten years will show a much greater percentage of successes than do the statistics up to date. As regards cerebellar tumors, however, the prognosis is not good. Only one-tenth of the cerebellum can be reached by the surgeon through the occipital fossa, as he has determined by measurements on the cadaver. This region is rarely the seat of cerebellar tumor. It is usually in the middle lobe of the cerebellum, directly beneath the tentorium, or lies in the sulcus between the cerebellum and the pons; both of these are inaccessible localities. He thinks, therefore, that the operation throughout is a futile one. The causes of failure in operations for brain tumor are: 1. Mistakes in the diagnosis. The local symptoms are not infallible. 2. Some tumors when accessible are not removable, such as infiltrating gliomata without boundary. The dangers of hemorrhage and meningitis are less dreaded than formerly, and proper asepsis prevents the latter complication in all cases.

58. **Paramyoclonus Multiplex (Friedreich's Type.)**—Hunt holds that there is considerable confusion in the nomenclature of this condition, which he thinks is generally spinal in its origin. His remarks are:

1. The term paramyoclonus multiplex, or myoclonus multiplex, should be reserved for that form of myospasm characterized by multiple, spontaneous, isolated contractions of individual muscles. 2. This type is peculiar and distinctive, and receives its most logical explanation in a disturbance of the spinal centers. 3. It should be carefully separated from the cerebral type of the myospasms, which are characterized by movements of a more or less co-ordinated type, as are observed in the *maladie de tic, tic convulsif* and the convulsive tremor of Pritchard and Hammond. 4. The contractions of paramyoclonus multiplex are closely related to the myokymia and fibrillary contractions. 5. Paramyoclonus multiplex may occur as an idiopathic or a deuteropathic affection, in the latter complicating various organic and functional diseases of cerebral and spinal origin.

63 *Transplantation of Arteries. Joshua C. Hubbard.
64 *The Effect of X-rays on Living Tissue. Seabury W. Allen.
65 On the Increase of Bacteriolytic Complements in the Rabbit's Blood. E. B. Vedder.

59. **Hodgkin's Disease.**—Simmons concludes from his analysis and study of cases that Hodgkin's disease should be regarded as a clinical entity, presenting a definite histologic picture. It has no relations to leukemia or tuberculosis, though the latter may co-exist. Eosinophiles are often, though not always, present in the glands. A considerable portion of his paper is taken up with a report of cases.

60. **Chancroid Bacillus.**—From his investigation Davis concludes that the accumulating evidence of the specific agency of the bacillus of Ducrey in the causation of chancroid justifies the following conclusions:

1. The organism is present in the purulent secretions of the great majority of cases of chancroid, and occasionally also in the pus of buboes, and may be identified by its morphology and staining reaction, together with its ability to grow on ordinary culture media. 2. Characteristic growth of the organism in a pure state may be obtained in suitable media from genital chancroids direct and also from chancroidal buboes in some cases. Growth is most luxuriant in a medium of fresh blood and bouillon, but unmixed human blood is the best medium for obtaining cultures from a source open to contamination. 3. Inoculation of a pure culture of the bacillus or of chancroidal pus on the skin of a certain species of monkey reproduces the lesion, from which in turn the original organism may be recovered in culture. 4. The cultivation of the same organism in a pure state from lesions on the hands, clinically resembling chancroid, in the absence of genital lesions, indicates that chancroid may be primary on an extragenital site. 5. Bacteriological examination of all ulcers of this type is likely to establish in the future a greater prevalence of extragenital chancroid than has hitherto been reported.

61. **Chronic Cystic Mastitis.**—From their analysis of 30 cases, Greenough and Hartwell conclude that the name "chronic cystic mastitis" (Koenig) is the best of many terms used to describe the condition of fibroid tissue increase and cystic formation in the breast at the time of the menopause. The term "mastitis" should not imply an inflammatory process due to bacteria, but rather an increase of fibrous tissue of other than local tumor origin. This increase of the fibrous tissue of the breast is normal in the stage of decline of the gland at the climacteric period. The formation of cysts and proliferation of the epithelium of the cysts and acini are striking features of the disease. Variations of the epithelium are found in this disease, from atrophic forms, through columnar cells, to papillary proliferation and cell masses of an adenomatous type. The transition of adenomatous proliferation to carcinoma of the adenocarcinoma type occurs in a few cases, but transition to other forms of cancer has not been observed. This danger is sufficient to make removal of the entire gland desirable in all but the very early and slight degrees of the affection. The operation to be advised is, as a rule, the subcutaneous resection of the entire gland without removal of the nipple. This is best done by means of the Thomas incision under the fold of the breast.

62. **Septic Peritonitis.**—Manahan has investigated the bacteriology of the fibrinous exudate in 19 cases of septic peritonitis. In 17 bacteria were found in the fibrin, pneumococci, streptococci, colon bacilli and *Bacillus aerogenes capsulatus.*

63. **Transplantation of Arteries.**—This is an account of experimental research by Hubbard, dogs being used. He was able in a number of cases to make an anastomosis which would not leak, and which transmitted circulation for the time being, but thrombosis followed in many of the cases. All of the experiments were carried out on the carotids. The same method could be employed on the aorta. In two animals he attempted to transfer branches of the aorta and controlled circulation long enough to perform the operation, though neither of the cases were successful so far as the anastomosis was concerned. He remarks that Matas has published the report of three cases of aneurism cured by suturing the sac, leaving a lumen when possible. This has, therefore, solved part of the problem he applied himself to solve, and by combining Matas' technic with his own, he thinks it might be possible to cure aneurism of the abdominal aorta. The aneurism could be sutured by the method of Matas, preserving its lumen, and any branches which arise from its sac and are too important to obliterate might be transferred to another portion of the aorta.

64. **The X-Rays.**—Allen finds:

1. The effect of prolonged *x*-ray exposures on vinegar worms and protozoa is fatal. 2. On superficial capillary circulation the effect is like that of an irritant, producing vaso-dilatation. The relief of pain in cases of deep malignant growths may be explained by this phenomenon. 3. On the heart in cold-blooded animals *x*-rays act as an inhibitor. 4. On growing plants the effect is distinctly stimulating, in fact over-stimulating. On full-grown plants it is not apparently harmful. 5. Exposures

produce immediately a local increase in the number of leucocytes in the blood. This is consistent with the irritant effect upon the skin and capillaries. 6. On surface malignant growths the effect is curative in a great majority of cases, the cure not necessarily being the result of necrosis. 7. On deep malignant growths there is no microscopic change to be found in the pathological or normal cell elements. 8. Excessive exposure on healthy skin produces sloughing of the superficial tissues, leaving a low-grade, sluggish ulceration which heals slowly or not at all. Permanent dilatation of the capillaries and a scarcity of granulation tissue and blood vessels are common in such ulcerations. 9. Clinical effects are not due to *x*-rays so much as they are to some other unknown, but closely allied, phenomenon.

73 The Effervescence Test for Gastric Acidity. A. L. Benedict.
74 A Further Development of the Benedict Effervescence Test for Gastric Acidity. Boardman Reed.
75 The Etiology of Hyperacidity. A. Robin.

66. **Hyperchlorhydria.**—This issue contains a symposium on hyperchlorhydria. A number of queries were submitted to various distinguished authorities, and their answers are given. The frequency of the condition seems to be variously estimated. Ewald, Küttner and McCaskey consider it by no means the most frequent of gastric disorders, while, on the other hand, Einhorn and Reed seem to think it outnumbers all other derangements. Von Noorden and Hemmeter are guarded in their answers in regard to the matter. The relation of hyperchlorhydria to gastric ulcer is also a point on which the authors differ, some holding that gastric ulcer causes hyperchlorhydria and others that it is a direct effect of it. As regards treatment, there are also differences of opinion, some believing in the free use of carbohydrates and fats and the withholding of meats, while others still allow the latter. The alkaline drug treatment seems to be the one in favor.

67. **Gastric Hypersecretion.**—Hayem finds the cause of hypersecretion to be the various forms of parenchymatous gastritis. It is probable that some of the vices of alimentary hygiene, which are the habitual causes of gastritis, act in a special manner on the glandular element, but it would be difficult to indicate them at the present time. An excess of food, especially nitrogenous, fermented beverages, and in women the compression of the waist by the corset, are the most frequent causes noted by him. The influence of heredity seems to be also incontestable.

69. **Hyperchlorhydria.**—Hemmeter recognizes two classes of this infection: 1. Those of a neurotic type in which there is a preponderance of nervous symptoms and fragments of the mucosa show no increase in the number of gland tubules or in the oxyntic or acid cells. 2. Those where there is an increase in the number of gland tubules or in the oxyntic cells. There is no sharp line between these two, but they require somewhat different treatment. In some cases the hyperacidity may be kept up by a proteid diet, though the latter may relieve the annoying symptoms for a time. If this relief is very brief, however, and the indican increases, then he advises a diet rich in carbohydrates and fats. All cases of hyperacidity require a certain amount of carbohydrates. In case of ulcer the diet must be as little irritating as possible.

70. **Treatment of Hyperchlorhydria.**—Turck goes at length into the mechanism of the symptoms and advises the use of demulcents as imitating Nature's method in throwing out mucus on the irritated stomach. To prevent the irritating action of water directly on the mucous membrane he has long advised the use of an intragastric bag, which will give the beneficial effects of heat in water without causing irritation. Water vapor, on the other hand, has a soothing effect, and is improved by the addition of volatile antiseptics, a few drops of oil of cloves, menthol, cinnamon, etc., added to half a gallon of water. He finds that these oils lessen the flow of hydrochloric acid rather than increase it. He describes the methods of forced feeding or gavage and the class of cases in which it is indicated, especially those in which the appetite fails, and there is repugnance to food, loss of weight, and where it is found desirable to so arrange the food as to coat the stomach with a bland substance, giving it in a mucilage of slippery elm, etc. One of the chief advantages of this is that the psychic gastric juice secretion is prevented, the odor of food and its taste being absent. In the severe forms, rest to the stomach is important in the initial treatment; putting the patient to bed and withholding all food for forty-eight hours, following this by one meal a day by gavage. The medication consists in the alkalies for neutralizing the acid and atropin to lessen secretion. In conclusion he mentions the Carlsbad mineral water and the French Lick spring water, which should be taken in small quantities, and the value of psychic treatment, gymnastic exercise and outdoor life.

July.

76 *Gastric Ulcer; Its Diagnosis and Indications for Surgical Intervention. A. F. Stewart.
77 Lectures on Gynecology. Franklin H. Martin.
78 Pathogenesis of Locomotor Ataxia. (Continued.) G. B. Hassin.

76. **Gastric Ulcer.**—Stewart thinks that gastric ulcer is more frequent than supposed, and that if we rely on the so-called classical symptoms, we will miss an early diagnosis in about 60 per cent. of cases. It may be reasonably held that a patient suffering from trouble in the right upper quadrant of the abdomen, unrelieved by medical treatment or suitable diet, probably has gastric ulcer or cholecystitis or both. Any medical treatment in which the hemoglobin fails to approximate the normal will fail, and surgical intervention is contraindicated with a low hemoglobin percentage and a high leucocytosis. The mechanical irritation of food in ulceration is a strong factor in the subsequent development of carcinoma; hence, gastro-enterostomy should be instituted early to secure the physiologic rest necessary to repair.

July.

79 *Effects of the Streptococcus on the Cortical Nerve Cell in Meningitis. Leonard K. Hirshberg.
80 *Is Cesarean Section Advisable in the Treatment of Placenta Previa? Henry D. Fry.

79. **Meningitis.**—Hirshberg has investigated and reports a case of meningitis with complete postmortem details and examination of the cortical brain cells. The infection in this case was clearly a streptococcic one, the organism being found by lumbar puncture during life and in cultures from the surfaces of the brain and spinal fluid after death. Sections taken from the cortex in the rolandic area, where the green purulent exudate was very thick, stained by Nissl's modified method, showed interesting changes. All of the Nissl (or tigroid bodies had entirely disappeared from the cell bodies, and many of the cells had lost their nuclei and took the stain poorly. The cells were shrunken, distorted and irregular where the nucleus remained, and it was swollen, vesicular, and its limiting membrane at times in contact with the body wall of the cell. The nucleus as well as the nucleolus was displaced in many cases. The changes were not exactly the same as those which Barker found in his case of epidemic cerebrospinal meningitis. The nuclei were more swollen and disorganization of the stainable substance of Nissl was more complete. This may be either a question of degree of intoxication, the author says, or it may show a distinct action of the streptococcic toxin. Though there may have been some effects from reaction at a distance, direct or immediate action of the toxins of the streptococcus is the most probable.

80. **Cesarean Section.**—Fry discusses the question as to the advisability of cesarean section in placenta previa, and concludes that it is advisable in a small proportion of cases when the woman is in good condition and has not been exhausted by prolonged labor or hemorrhage, and when the placenta is implanted centrally, or nearly so, and when the cervix is un-

dilated and undilatable. He thinks it increases the chances of saving the infants better than other methods.

81. Psychiatric Progress.—Dr. Blumer's presidential address reviews the subject of psychiatric progress, noticing the advances of the clinical school, as shown by the acceptance of Kraepelin's teachings, and its services to the profession. The reformation of the New York State Hospital services are remarked on and the development of the tendency to centralization and politics which is criticised. Blumer notices the increase of insanity, showing that it is a fact and giving data making an estimate of the number of insane in new England alone as 1 to every 307 individuals. The question whether we are doing all in our power for the prevention of insanity is also raised, with special reference to the increase of degenerates by their intermarriage and by marriages of consanguinity. In conclusion, he remarks on the more rigid laws recently enforced, partly through the efforts of the New York State Commission on Lunacy, in regard to the prevention of immigration into this country.

86. Posterior Cervicovaginal Fixation.—The operation described by Goelet aims at overcoming retroversion by holding the cervix permanently backward in the hollow of the sacrum and doing away with the pessary. Its success depends on the close attachment of the vagina to the rectum, especially in its upper portion. Its field of usefulness is restricted to cases where communication between the vagina and rectum is not too loose or the latter is not permanently dilated. The operation consists in denuding an area about one-half an inch square on the posterior surface of the cervix, and a similar surface on the posterior vaginal wall, well up in the sulcus behind the cervix, is likewise denuded; approximating the parts by deep sutures inserted from in front backward under the denuded area of the cervix and from behind forward under that of the vaginal wall. Three or four of these will usually suffice, and when they are tied the cervix is drawn backward and the fundus thrown forward. The suture material used is silkworm gut, stained with methylene blue to render it more conspicuous for convenience in removal. A tampon of gauze is placed against the cervix to take the strain off the sutures and keep the surface dry. It is removed on the second day, and may be renewed or not, according to the surgeon's judgment. The patient is kept in bed for a week, but is encouraged to rest on either side rather than on the back, and when she gets up is advised to use moderate care for two or three weeks to avoid exertion that might cause a strain on the parts. The sutures are not removed until the end of the second or third week or not until it is certain that firm union has been secured. He thinks the operation has a future, though its adaptability is somewhat limited.

8 Note on the Operation for Cleft Palate. Charles P. Childe.

1. **Cancer of the Prostate.**—Harrison holds that carcinoma of the prostate is far more common than has been held. The disorder is not infrequently met in younger persons than those suffering from the ordinary forms of prostatic enlargement or adenoma. It may occur at or about the age of 50. It is usually associated with considerable lumbar and sciatic pains, and involves the glands in the groin. Rectal examination shows a hard stony gland with fixedness. Slight hemorrhages are common, but there may be only a late obstruction to catheterism. Loss of weight is usually noted. The conditions are very different from those of ordinary adenomatous enlargement. He insists on the use of the electric cystoscope to confirm the diagnosis on account of its importance at the present time, when operations are frequent. Prostatectomy is not so urgently indicated in the early stages of cancer and the prospect of recurrences should be fully considered. If urinary obstruction, however, exists, a suprapubic opening may give immense relief. The paper also includes remarks on partial operation for prostatectomy, the removal of a limited portion of the gland, and in conclusion he suggests the possibility of stricture following operations and due to laceration of the prostatic urethra.

3. **Prostatic Obstruction.**—According to Clarke there are at least three conditions of prostatic obstruction quite independent of one another, and depending on several pathologic conditions: 1. Adenomatous growths; 2, the sclerotic type; 3, a condition of enlarged veins in connection with the organ, and there is also a fourth condition of inflammation and congestion of the mucous membrane surrounding the urethral orifice and all of these possibilities should be considered in our treatment.

17 *The Ortol Reaction as a Means of Distinguishing Raw Milk from Boiled. Carstairs C. Douglas.

9. **Bright's Disease.**—Bradford points out the distinction of Bright's disease from nephritis. The latter may be simply the result of toxic action from infectious disease, from renal infarction, or from drug intoxication. Bright's disease, on the other hand, has for its characteristic onset not merely urinary changes but also sudden occurrence of dropsy, peculiar in its character and distribution. In acute Bright's disease there is always a diminution of urine and a varying degree of albuminuria. In some cases the urine is also loaded with blood, but cases of very acute Bright's disease with marked dropsy may occur with little or no blood in the urine or little or no albuminuria. Chronic Bright's disease is difficult to classify, but he recognizes two fundamental varieties: 1. A more or less close correspondence with the condition described as large, white kidney, though the kidneys are frequently not greatly enlarged. This may follow an attack of acute Bright's disease or may be the final result of a number of recurrent attacks or it may be chronic or persistent from the beginning. The second form has caused much difference of opinion. Some include it under the general category of granular kidney, and there is undoubtedly some resemblance in the symptoms. There is a sharp distinction, however, in the presence of a large amount of albuminuria, anemia, emaciation, etc., so marked in Bright's disease, which is often lacking in true granular kidney. In both forms we have a large quantity of dilute, highly alkaline urine; in both the dropsy is likely to be absent and it is by no means uncommon for chronic Bright's disease to be discovered when not expected, especially the second type. The progressive loss of strength and flesh is most characteristic. Another not uncommon feature is the presence of pigmentation which has often led to the diagnosis of Addison's disease. There is a marked neuroretinitis in most cases and the suggestion of an unrecorded form of chlorosis is sometimes possible. There are some syphilitic conditions which are undistinguishable in many respects from Bright's disease, but the results of treatment and the history will clear matters up. He sums up, therefore, the four different types of Bright's disease or related forms, as: 1. Nephritis; 2, Bright's disease; 3, two different forms of chronic Bright's disease, and 4, granular kidney. The anatomic conditions and the etiology have considerable in common, but the author's conclusion is that we may regard the various forms of nephritis as produced by a toxic agent on the kidney and in Bright's disease with dropsy the toxic agent acts not only on the kidney but on the vessels generally. The diagnosis is not usually difficult, especially in the acute form, but as already indicated, it may be troublesome in the chronic type where the renal symptoms are not prominent and the separation of Bright's disease from amyloid disease is a matter of importance on account of the difference in treatment. The character of the urine and sometimes the presence of waxy casts and the recognition of a cause capable of producing amyloid degeneration will generally aid in the differentiation. The differential diagnosis from the more passive congestion, especially in cardiac cases, is an important one from a prognostic point of view. Usually the character of the casts in the two cases, the difference in the specific gravity in the urine and the fact that renal congestion is most likely to be present where there are other signs of distension of the venous system, will aid the diagnosis. In some forms of heart disease with albuminuria it is very difficult to say which is primary.

12. **Chloroform.**—Guthrie recalls a former article in which he reported a number of cases of death occurring within ten hours to six days after operation was performed under chloroform in children and one case in which recovery took place after very serious symptoms. In these fatal cases he found a peculiar fatty degeneration of the liver, and he remarks that the chloroform may have been responsible as against the possibility of carbolic acid poisoning which was suggested as the cause of death in some of his cases in which antiseptics were used in the preparation for operation. There is no doubt in these cases of the carbolic acid poisoning, but he does not consider

that the principal factor. Experiments on animals show that generally fatty degeneration is the result of chloroform narcosis, but it is more difficult to suppose that this might be followed by death from anesthesia of only an hour or so. From the facts presented, he thinks it is probable that the liver being in an advanced state of fattiness previous to operation, was probably on the verge of functional inadequacy with regard to elimination of toxins entering the portal circulation, though still able to hold its own in ordinary circumstances. Chloroform aggravated the condition and lowered the hepatic function so that ptomains or toxins escaped into the general circulation, or by their specific action on the kidneys prevented the elimination of such poison. These are the conclusions of his former paper. He remarks on the possibility of foreseeing whether chloroform will be dangerous in a given case, and refers to Poehl's statement that the quantity of alkaline substance may be a guide. Whether this has been proven to be a face he does not know, but there are practical difficulties in the thorough examination of the urine to the extent required. He also suggests a possibility of danger in the practice of utilizing phloridzin before operations to test the adequacy of the kidneys. It has, according to Romfeld, the effect of causing a storage of fat in the liver. The diagnosis of these cases is not difficult when we consider the cerebral symptoms and delirium which is noted. Jaundice was only present in one case. The treatment which he would recommend would be the use of stimulants, active purgation, venesection and saline transfusion. There is no use to wait until the chold is comatose before resorting to these measures.

15. **Diet in Pregnancy.**—Paton has investigated the effect of diet on the weight of the newborn, and finds that observations, though not numerous, agree so closely that they warrant the conclusion that the size of the offspring depends very directly on the diet and nutrition of the mother during pregnancy. While this explains the easy labors among the healthy lower classes and confirms Prochownick's conclusion that by dieting the mother the children of rickety women may be so reduced in size as to be viable, it also helps to explain the very high infant mortality among the very poor. The physiologic point of chief interest seems to be the demonstration of the limitations in the extent to which the tissues of the mother can be utilized for the construction of the embryo. The nutrition of the maternal tissues seems to take precedence over the nutrition of the fetus. If this were not the case, we would find that badly nourished mothers produce a greater proportion of weight than well-nourished mothers, which is the reverse of what occurs. The mother thus appears to pass on the surplus nourishment to the fetus and the better the nourishment of the maternal tissues the greater the growth of the young *in utero*.

17. **The Ortol Reaction.**—Douglas calls attention to the color reaction recently described by Saul in the *British Medical Journal*, which he has employed in a number of cases. It is simply the adding of a few drops of a 1 per cent. solution of an organic compound, ortlomethyl-aminophenyl-sulphate to raw milk or milk which has not been raised above a certain temperature and following it by a drop of weak peroxid and hydrogen (5 volume strength), which produces in a very short time a deep reddish-pink color. When this is carried out on milk that has been heated above the pasteurization point (above 75. C) or a little higher, this reaction fails, or only a slight brownish tinge is given. As the compound is expensive, Saul advises the use of ortol instead, a substance used in photography, and consisting of the above body mixed with quinol. Douglas has always employed it, and for the sake of convenience calls the test the ortol reaction.

19 Some Septic Infections and Nervous Lesions Following Chancroids. E. F. Gordon Tucker.
20 Note on the Climate of Erythrea. G. M. Giles.
21 Note on the Mycoid Body Found in the Blood Corpuscles in Remittent Fevers. (Continued.) W. Leonard Braddon.

18. **Vesical Calculus.**—Hatch has had considerable experience with stone in the bladder in Bombay, and gives his views. As regards lateral lithotomy he thinks there are very few occasions in which it can be used in adults with advantage. The possibilities of causing urine incontinence and also of opening the peritoneum are decidedly against it. As regards litholapaxy in the ordinary uncomplicated cases in adults it is almost an ideal operation, and he thinks the perineal method has not been sufficiently valued and utilized. The operation requires skill on the part of the operator, and especially in children where the tissues tear easily and the parts are small. The anesthetizing is an important matter in these cases, and it is impossible to seize and crush the fragments unless the bladder walls are passive, and sometimes the use of instruments sets up a movement which may hamper, if not destroy, the possibility of further progress. Without a skillful anesthetist he would hesitate to operate by crushing. Suprapubic lithotomy he thinks undesirable in adults, excepting in a case of very large stone. It is slow in healing, and the accumulation of phosphates, etc., causes an irritation, and the patient sometimes dies from exhaustion. In any case he thinks it is well to drain through the perineal urethra. It does not increase the risk, and only takes a few minutes. In children, however, the operation is a good one. The bladder is naturally high, is easily raised above the pubis, readily opened without danger to the peritoneum, its contents can be easily removed, and subsequent suturing carried out with facility. For men engaged in general practice, as opposed to hospital practice, the operation is much safer than litholapaxy in children. Cystitis is also less likely to occur in children. Cutting is, therefore, more cleanly and the incision heals better. With small stones and roomy passages, it is often possible to remove the calculus by a good-sized evacuating canula. He has several times succeeded by this method. He does not find many cases of encysted stone, indeed has had but one case where it was unreachable by the lithotrite. In this case the suprapubic operation was required. The mortality of the suprapubic operation in his cases was about 32 per cent.; in his perineal lithotomies about 10 per cent.; of 352 litholapaxies only 16 died, or 4.5 per cent. His tabulation does not include a series of two hundred or more cases where sufficient data were lacking for publication, but the results of these two hundred averaged rather more favorably than those reported. The patients were of a better class, mostly from outside the city, and in better physical condition.

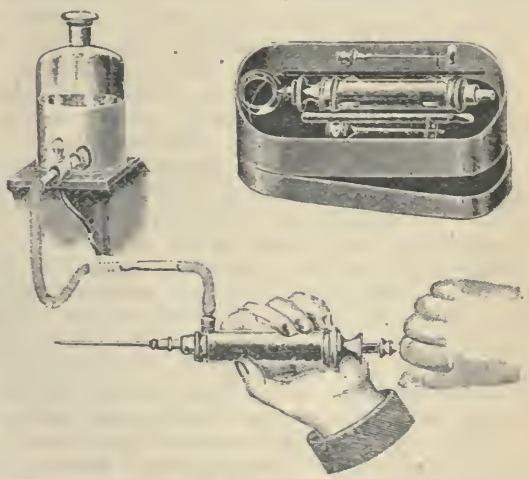
42 (No. 11.) Role de la prostate dans les tumeurs epithéliales infiltrées de la vessie (of bladder). E. Monfort.

23. **Experimental Tuberculosis of Genito-Urinary Organs.**—Hansen found it impossible to induce hematogenic tuberculosis of the bladder in his experiments on rabbits, even after contusion of the organ and simultaneous subcutaneous injection of tubercle bacilli. But direct inoculation proved successful, especially when accompanied by transient retention of urine. The resulting lesion was generally insignificant and displayed no tendency to spread by way of the ureters to the kidney, but it almost invariably involved the prostatic vesicle and the prostate itself. Inoculations in the lower portion of the vas deferens induced tuberculous lesions, not only in the testicle and epididymis, but also in the vas and prostatic vesicle. In one instance the prostate was likewise invaded, but never the bladder, and still less the ureters or kidneys. In one single case injection into the ureter, plus ligature, was successful in inducing a tuberculous lesion in the kidney.

26 and 30. **Intravesical Segregation of Urine.**—The instruments devised by Luys and Cathelin have been described in THE JOURNAL from time to time during the past year. Luys has found a small size useful for children. See THE JOURNAL, xl, p. 62, ¶39.

31. **Influence of Resection of Vas Deferens on Vesical Sphincter.**—Wassilieff ascribes to reflex action on the tonus of the bladder sphincter the favorable results observed after resection of the vas deferens in case of hypertrophy of the prostate. He has been led to this conclusion by the constant results in a series of experiments on dogs. This explains the promptness with which the result is attained, sometimes in a few hours. The suppression of the spasmodic contraction of the sphincter affords better conditions for drainage of the bladder thereafter, and this ensures continuous and prolonged benefit. The most brilliant successes in these sexual operations have been obtained in cases of acute retention. Pankreatieff reported in 1900 that only 3 failures had been observed in 39 cases belonging to this category. In the experimental research described the degree of intravesical pressure necessary to emit the urine was determined before and after the intervention, and in every instance resection of the vas reduced the tonicity of the sphincter.



32. **Double Bladder.**—Cathelin gives the details of 17 doubtful but probable cases of double bladder that he found in the literature, and of 15 certain cases, including one personally observed. In the latter a man of 82 died in urinary cachexia from complete retention. Two bladders were found, both about the same size and located one behind the other. The right ureter opened into the anterior and the left into the posterior organ.

34. **Linear Electrolysis for Urethral Stricture.**—André concludes from study of 23 cases that this method of treating a stricture may be indicated when it is not multiple or not more than three; when the stricture is not too hard, and especially when it is merely a narrow belt and the urethra is not constricted for any distance. Under these conditions electrolysis is to be preferred to urethrotomy on account of the simplicity of the intervention and the lack of necessity for after-care. But it is very important that the dilation realized should be maintained by occasionally passing a bougie, as after any method of treating stricture. Neglect of this precaution may undo all the benefits derived, as he has learned from his experience.

36. **Flat Catheter for Hypertrophied Prostate.**—Bartrina has found that the hypertrophied prostate frequently nearly closes up the orifice into the bladder, but leaves a long, narrow slit. In these conditions he has found that a catheter made flat instead of round could be readily passed through the slit, when it was impossible to introduce ordinary round catheters even of a much smaller size.

37. **Ablation of Suppurating Buboes.**—Pousson treats suppurating venereal inguinal adenites the same as a malignant neoplasm. He removes the entire infected pleiad of ganglia with the gland involved. His patients were dismissed cured in fifteen to twenty days, and he is convinced that better results follow this method of treatment.

38. **Improved Technic of Epidural Injections.**—A. Strauss of Barmen has introduced Cathelin's epidural injections into Germany, modifying the technic somewhat. He is preparing an address on the subject for the approaching Naturforscher Congress in Germany, and in the meantime has published a work on the subject extolling the method as important progress. Cathelin and Strauss both claim that this method of spinal cocainization is free from the dangers of the subarachnoid route as also from its inconveniences, while it is at least fully as effective. (Cathelin's technic was described in THE JOURNAL, xxxviii, 1902, p. 1279, ¶60.) Strauss announces that the lowest limit of efficacy of the cocain solution, .02 per cent., can be reduced by one-half if it is dissolved in physiologic salt solution. His formula is: .2 sodium chlorid; .01 cocain hydrochlorate in 100 gm. distilled water, with the addition of 2 drops of 5 per cent. carbonated water. He has invented a syringe which fills itself automatically and is peculiarly adapted for this work, and also for infiltration anesthesia as it has a double valve arrangement allowing both aspiration and expulsion.

He uses a platinum needle about 6 cm. long and 1 mm. in diameter, kept very sharp. Cathelin gives illustrations showing the various points in the technic.

39. **Tuberculosis of the Urinary Apparatus.**—In the second part of this important contribution and review of the vast material at the Necker Hospital, tuberculosis of the posterior urethra, prostate and seminal vesicles is considered, with 44 cuts. Rectal exploration is the only effectual mode of investigating the condition of the prostate. Increase in size and tension reveal the perituberculous congestion. The finger sinks in, the tumefied organ feeling like a uniform, pasty mass. In the atrophic, sclerous form, frequently one phase of healing, the organ will be found diminished in size and indurated. Palpation of the vesicles reveals the same pasty consistency. Expression of the prostatic juice by massage through the rectum is liable to reveal the Koch bacillus. A subvesical cavity is suggested when the forcible evacuation of urine is followed by a dribbling from the pocket below the bladder. Hemorrhage may also occur from the pocket, as hemoptysis from a cavity in the lung. The pocket may be palpated through the rectum and its contents evacuated. The feeling through the rectum of a catheter in the cavity is also characteristic. The prognosis of tuberculosis in the posterior urethra is grave, but tubercles in the prostate and seminal vesicles are liable to heal. A perituberculous reaction on the part of the connective tissue may arrest and cure the tuberculous focus, and the possibility of this contingency should always be borne in mind. Secondary infection is liable to prove disastrous and catheterization should therefore be restricted to the minimum. The possibility that the tuberculous focus is single is slight. Saxtorph found only 9 cases of an isolated focus in the prostate and 2 in the vesicles in 205 cases of chronic urogenital tuberculosis. On the

other hand, the pathologic anatomists find a marked tendency to encystment of the lesions. At the Necker Hospital many cases of actual spontaneous cures by this process of sclerosis have been encountered, and the clinic confirms the possibility of spontaneous cure of tuberculosis of the testicles, prostate and vesicles. The surgeon should, therefore, refrain from precipitate intervention. Vigorous medical, hygienic and medicinal measures should be instituted, refraining from all instrumental or topical treatment. If the affection continues a progressive course, threatening softening and suppuration, the surgeon should proceed to forestall the pathologic destruction of the organs by suppressing the focus. The prostate and vesicles should be removed if the lesions in them are extensive and softening has already occurred, liable by their further progress to endanger life. The results will be good, barring complications elsewhere. Even in an advanced stage, regardless of the general condition, surgical intervention may sometimes be useful. By evacuating a large subvesical cavity through the perineum, draining and diverting the course of the urine to obviate stagnation and its general effects, the surgeon will frequently relieve and may sometimes cure.

40. **Cancer of the Prostate.**—Oraison has observed 2 cases of primary cancer of the prostate. Twenty-eight cases have been encountered at the Necker Hospital in the course of three years in a total of 306 prostatic subjects, and 16 at Saint-André in twelve years, in a total of 170. Albarran and Hallé found 14 epitheliomata of the prostate in 100 cadavers which had been labeled as merely hypertrophy of the organ. They were the first to describe the circumscribed variety, adenoid epithelioma. Neoplasms in the prostate are usually observed under 10 or over 50 years of age. In young subjects sarcomata of the prostate are more frequent and epitheliomata in the elderly. The above writers have published 10 cases in which simple hypertrophy of the prostate became transformed into a malignant neoplasm. Socin, Klebs and Thompson have met with 3 more. Different varieties of cancer have been found in the prostate, carcinoma 48, and sarcoma 7 in 55. In 10 cases on record operated on more than four years ago, the cure has persisted to date. In 6 cases there was an operative cure, and in 4 the patients died during or soon after surgical intervention. In 3 others recurrence followed in nine to fourteen months. The conclusions imposed by experience and review of the literature are that every suspicious case of hypertrophy of the prostate causing symptoms sufficiently annoying to justify intervention, should be treated by prostatectomy, according to Albarran, and very frequently the lesion will prove to have a tendency to malignancy. Even when a cure is not possible, an operation may afford great relief. Subtotal prostatectomy will usually answer unless the prostatic urethra be likewise involved. When the cancer has passed beyond the limits of the gland abstention is the wisest course.

41. **Massage in Treatment of Urethral Strictures.**—Bartrina first fills the bladder with a 1 per 2,000 solution of mercury oxycyanid and then dilates the strictures with two or three catheters, as usual, at each sitting, massaging the urethra for five minutes over each catheter in turn. These procedures summon the leucocytes to the spot, but in order to reach it they have to pass the zone of the stricture sclerosis. In order to cross this zone the leucocytes have to make a way for themselves through the interstices of the fibrous tissue. By this microscopic burrowing through the tissue its trabeculæ become less compact, the meshes are stretched and the tissue becomes more flexible. The leucocytes also bring away with them the infiltrates in the glands and sweep them clean as it were. Massage is therefore indicated to promote absorption, and as a preventive measure in case of infiltration to prevent its becoming organized into sclerous tissue. It is especially effective in the treatment of chronic urethritis, which so often accompanies a stricture, but its chief value lies in its modification of the stricture itself.

44 *Dilatation aortique rheumatismale. Zuber.

45 *Propriétés du sérum antidiphthérique. L. Martin.

43. **Early Paralysis of Soft Palate in Diphtheria.**—Deguy suggests that there is a secondary infectious factor in these paralyses as well as a toxic. Five cases which he reports confirm this assumption.

44. **Dilation of Aorta from Rheumatism.**—Zuber has had occasion to observe two cases of this condition, and has traced one for three years. The lad is now 16 and has had seven attacks of acute articular rheumatism. The aortitis has continued a progressive course and the aorta is now enormously dilated.

45. **Antidiphtheria Serum Tablets.**—In this communication from the Paris Pasteur Institute Martin states that he has established that the curative serums contain a sensibilizing substance when they are able to induce agglutination, which ordinary serums do not have. He also announces that antidiphtheria serum applied locally to the throat in case of diphtheria rapidly reduced the pain in all his experiences. Local applications are too transient for much benefit to be derived in this way and still better results are attained by incorporating dried serum with some vehicle which slowly dissolves in the mouth. Tests of serum tablets thus made and given to adults and older children, showed that the pain rapidly subsided under their influence, the membranes turned yellow, swelled, and were soon cast off. Cultures taken from the throats after using these tablets showed that a much smaller number of colonies developed after twenty-four hours than in control cultures, and very few could be discovered after forty-eight hours. His experience demonstrates that the persistence of the diphtheria bacilli in the throat can be diminished by using these tablets, and that they will also serve as a prophylactic measure. He never failed to make the usual subcutaneous injections of the serum in cases of established diphtheria, and regards the tablets in such conditions as merely an adjuvant until further orders.

68 Die transpleurale Laparotomie und die offenen Milzwunden (open spleen injuries). F. Schaefer.

48. **Adenomata of Intestines.**—Smoler's experience includes 8 cases of polypi in the rectum observed at the Prague clinic,

and he reviews 12 in the literature. He also describes a typical case of adenoma in the small intestine, with 5 collected, and 15 cases of adenomata in the large intestine. On this basis he describes the clinical picture, prognosis and treatment.

49. **Autoplastic Treatment of Spina Ventosa.**—Tilmann advocates Müller's method of substituting the diaphysis of the metacarpus by a fragment of bone taken from the ulna with its periosteum. One of the advantages of this method is that both wounds are near enough together to be dressed with the same bandage. He has thus treated 13 cases, and remarks that this method can be considered comparatively certain and the resulting function good, although induration or a fistula may persist in some cases for a time. He emphasizes the necessity of taking a larger piece of bone for the substitute flap the younger the subject.

50. **Mal Perforans.**—In 6 of the 14 cases reported from the Zurich clinic no causal factor could be determined, but in the others there was evident degeneration of the nerve or vascular sclerosis.

51. **Surgery of Injuries of Spleen and Liver.**—Roeser is able to report 2 severe cases of rupture of the spleen and hemorrhage into the abdominal cavity which were cured by an abdominal splenectomy. In the third case, a stab wound was merely tamponed, and the patient succumbed to metastatic pneumonia. He also describes 5 cases of injury of the liver treated by surgical intervention.

53. **Treatment of Internal Intestinal Obstruction.**—Hepner reviews the published statistics of certain German clinics in addition to Riegner's at Breslau, and concludes that the best results are obtained when attention is paid chiefly to improving the conditions of the circulation and relieving the overfilled intestine. In Riegner's experience with 37 cases, operative intervention was required in 31, and 15 of these recovered. The palpation findings were positive in 17 of the 31, in 12 negative and in 2 misleading. He thinks the indication to relieve the distended intestine is as urgent as to make a correct diagnosis by palpation beforehand. Hepner describes the cases in detail.

54. **Experimental Infectious Thrombosis.**—Talke found that thrombosis occurred in 33 experiments out of 44, in which he inoculated rabbits, cats or dogs with staphylococci in the vicinity of a vein or artery. In 16 cases the thrombi completely obliterated the vessel, and in 12 only partially closed the lumen. Thrombosis was noted as early as nine hours after the inoculation. He describes the histologic findings; they suggest that the thrombosis occurred indirectly, by the intermediation of inflammatory alterations.

55. **Changes in Joints in Syringomyelia.**—In 17 cases of syringomyelia observed at von Bruns' clinic, the joints were affected, the shoulder in 12, elbow in 4, wrist, hip, knee or ankle in one each. This represents 30 per cent. of the total number of cases of syringomyelia observed during the last forty years at the clinic. Men were affected more frequently than women, and trauma seemed to be an important factor. The joint affection is slow and chronic, and in only 2 cases was operative intervention required. Sokoloff noted joint troubles in 10 per cent., and Schlesinger in 25 per cent., in their experience with syringomyelia.

57. **Autointoxication in Case of Intestinal Occlusion.**—The experimental researches reported apparently demonstrate that the passage of the bacterium coli into the blood and tissues, in case of intestinal occlusion, is the cause of the general symptoms observed. Indicanuria was noted in 85.7 per cent. of the cases after occlusion of the small intestine; in 19 per cent. after occlusion of the large intestine, and in 20 per cent. after occlusion of the cecum The bacterium coli was found very early in the blood and in the abdominal cavity in a large proportion of the experiments.

58. **Mercury Massage for Fingers and Hands.**—Hofmeister describes a gentle means of massaging the hand in use at von Bruns' clinic. The patient is seated and dips the finger or hand gradually into an iron cylinder about 12 to 15 cm. in diameter and 50 cm. high, half full of quicksilver. A layer of 30 per cent. alcohol on top, a few centimeters thick, prevents evaporation or loss of the metal by its sticking to the hand or arm. Any wound on the fingers is protected by an adhesive plaster. The single sittings are from a quarter to an hour long, and the absolute painlessness, the regularity and the gradual way in which the hand can be immersed in the quicksilver at rhythmic intervals, commend this new massage procedure for general adoption. The only drawback is the expense of the quicksilver.

59. **Prospects of Operative Treatment of Mammary Cancer.**—Küttner reports from the same clinic that not a single one has survived to date out of the 41 cases of mammary cancer, operated on between 1880 and 1892, in which the supraclavicular glands were enlarged. All the apparently morbid elements were removed at the intervention. He reviews the details of 54 cases in which the supraclavicular glands were thus removed with the cancer.

60. **Treatment of Varices by the Madelung Method.**—Fraenkel states that extremely favorable remote results were obtained in 16 out of 21 cases of severe varices on the leg treated by shelling out the varicose veins. In 3 no appreciable benefit was derived, and 2 were merely improved. This operation has been performed at the Nuremberg clinic in 9 other cases also, of more recent date, a total of 35 operations on 30 patients, 7 of whom were women. Healing proceeded smoothly in all but 3 cases, in which there was moderate necrosis of the skin. This method of operating is reserved for the severer cases, in which operative intervention is indicated by the recurring neuralgic pains, cramps in the calves, swelling, hemorrhage or danger of it, obstinate eczema or ulcers. Such cases may call for the most radical ablation of the morbid venous network with excision of the saphena magna up into the thigh nearly to the fossa ovalis. Only in case such an extensive operation is absolutely contraindicated by the danger of the narcosis or other reason, is the Trendelenburg method preferable, that is, resection of a portion of the vein about 10 cm. long, just below its mouth. The technic of both methods of surgical intervention is described in detail. For the first, after a day or so of preparation the leg is wrapped in a sterile cloth and allowed to depend over the side of the bed for a few minutes, after which elastic constriction is applied at the root of the member, and under general narcosis the incision, starting at the fossa ovalis, exposes the saphena, which is resected between two ligatures. The peripheral threads are not cut but serve to locate the vein. The shelling out is more difficult below the knee, and several incisions may be necessary to avoid too much undermining of the skin. He uses fine silk to ligate the lumina and closes the long incision without drainage. The leg is placed in side splints and raised as high as 60 cm. for a week and then gradually lowered.

61. **Krause Flaps.**—The chief point in transplanting unpedunculated flaps is to keep them in place with catgut sutures. Widman describes 29 cases. In 11 the flap was applied on a finger after amputation, in 4 after removal of a tumor, in 5 after excision on account of lupus, disfiguring scars or traumatic defects.

63. **Treatment of Recent Fracture of the Patella.**—This article, with the 7 others preceding or following, issues from the Nuremberg clinic. In operative intervention in 5 cases of fractured patella the parts healed smoothly and the functional results are most excellent. Contact with the fingers in operating is scrupulously avoided, the joint cleaned with saline solution and fixation accomplished by an electric drill and silver wire. The wound is closed without drainage. Thienger lays great stress on the after-treatment, massage, suspension, etc. The patients are allowed to get up the fourth week, still wearing an immobilizing apparatus.

64. **Aberrant Tissue from Prostate.**—Thorel describes some very small tumors found by chance between the mouths of the ureters in the bladder at 4 autopsies of men between 20 and 59. Histologic investigation disclosed a structure similar to that of the prostate, and he thinks that certain cases of adenomatous neoformations in the bladder may be due to aberrant elements from the prostate.

71. **Bacteria and the Ciliated Epithelium of the Accessory Cavities.**—Törne found in calves and cadavers examined within two hours after death that the nasal accessory cavities were always sterile. He assumes that the ciliary movements are an important factor in preventing the entrance of bacteria.

78. **Stain for Flagella.**—Gemelli states that the flagella show up beautifully by the simple stain he describes, and that it never fails. He has studied with it the typhoid, colon and cholera germs, proteus, etc. The best media for this purpose are made with glycerin. A loop of the culture is diluted with 5 c.c. of distilled water on a watch glass, and one drop of the mixture is transferred to a boiled cover glass just taken out of alcohol. It is then dried under glass. The cover glass is then placed for ten to twenty minutes in a solution of 25 cg. potassium permanganate in 100 gm. distilled water. The cover glass is then rinsed in distilled water and placed in a stain made by adding 1 per cent. neutral red solution to a solution of .75 gm. calcium chlorid in 100 gm. distilled water, in the proportion of 20 to 1. The cover glass is left in this fluid for fifteen to thirty minutes. It is then rinsed, dried with blotting paper and mounted in balsam.

90. **The Appendix in Gynecologic Affections.**—Hermes thinks that the appendix is sometimes responsible for affections of the internal genitals, and advises examining it whenever the abdomen is opened for any cause. If signs of inflammation are found in the appendix it should be removed, especially if accompanied by adhesions.

96. **Phlebarteriectasia.**—Löwen does not refer to varicose aneurism, but merely to general diffuse dilatation of the veins and arteries without communication between them, as he observed in a case recently in his charge. The patient was a locksmith, 43 years of age, and one arm was affected. After excision of the radial dilatations the pains in the fingers were relieved, and he was able to return to his occupation. The affection gradually progressed and amputation is being considered as the last resort. This was done in 4 out of the 6 cases of the condition found in the literature, always forced by threatening hemorrhage. Löwen adds a list of nineteen works on the subject, but it contains no American names. In 3 of the 7 cases the right arm and in 4 the left was affected, and all the subjects were men, with one exception.

100. **Statistics of Operative-Treated Aneurisms.**—This communication issues from Braun's clinic at Göttingen. In the first part the history of operative treatment of idiopathic aneurism of the subclavian is reviewed, with a bibliography of 94 references and 21 new cases collected since Souchon's statistics of 81 in 1890. In the 21 new cases there were 17 men and 1 woman; the right subclavian was affected in 12 and the left in 5. In 19 cases followed for sufficient length of time 13 were permanently improved and 3 definitely cured. Treatment by distal ligature has 3 improvements out of 5 to its credit; proximal ligature, 5 out of 7; both distal and proximal, 1 out of 2, and extirpation, 3 cures out of 4 cases. The general conclusions of the work are that extirpation is the ideal method of treatment. It not only guarantees a radical cure, but also prevents the pains liable to occur after the aneurism has been obliterated by thrombi. Extirpation is not practicable if the walls are thin and pulsating unless the aneurism is very small and free from adhesions, or if large, is partially obliterated with thrombi. In case the aneurism is adherent to the clavicle and subclavian vein, the parts involved must be resected too. When extirpation is impossible, proximal ligature is next advisable. If the contents of the sac do not become solid after central ligature, a distal one should be applied. The latter alone offers little prospect of a cure. In case operative treatment is impossible Macewen's method of introducing needles and scratching the walls certainly deserves attention, as it proved successful in one case in his experience. As a last resort, electrolysis and "filipuncture" might be tried. Each has one case of improvement to its credit. Judgment is still in suspense in regard to the efficacy of gelatin injections.

The second part of the work is devoted to aneurism of the aorta, reviewing 13 new cases in addition to the 34 of previous statistics. In 10 the thoracic aorta was involved, and in 3 the abdominal. The results of operative treatment demonstrate that simultaneous ligature of the right carotid and subclavian in case of aneurism of the ascending aorta can not be considered a particularly dangerous operation. In a number of cases it was followed by improvement in both the subjective and objective symptoms. The same remarks apply also to ligature of the left carotid or simultaneous ligation of the left and subclavian in case of aneurism of the arch. Reports of the ultimate outcome of the cases on record are needed before final judgment can be passed on this operative treatment.

102. **Acute Prostatitis After Furunculosis.**—In the case described, as also in 4 found in the literature, the inflammation and abscess formation in the prostate originated in hemato-

genic infection. In 3 there was pyemic metastasis. The abscess should be incised and evacuated as soon as diagnosis is possible.

103. **Hernia in Young Children.**—In Grunert's 34 cases all were boys but one, and phimosis was noted in 13. The frequency of this coincidence of phimosis suggests some causal connection, and that circumcision might be useful in prophylaxis. None of these patients were Jews.

111 Investigations on Poisonous Rice. J. Sakaki.
112 *Tuberculosis.
113 *Public Health in Japan.

109. **Weight of the Brain of the Japanese.**—Taguchi compares the weight of the brain as noted in 397 male subjects, with similar statistics in England. It ranges from 1,345 gm. between 14 and 20, to 1391 between 40 and 50, and declines to 1,333 between 70 and 80. The corresponding English averages for 699 subjects were 1,376 gm., 1,360 and 1,290. The Japanese male brain, therefore, averages higher than the English, as also the female brain. It averaged 1,246 to 1,130 gm. for 766 English women and from 1,264 to 1,102 for 156 Japanese.

112. **Communicability of Tuberculosis.**—An editorial announces that in October, 1901, twelve healthy cows were inoculated with human tubercle bacilli in some official tests at the "Cattle Epidemic Laboratory of the Department of Agriculture and Commerce." In March, 1902, the cows all responded to tuberculin with a pronounced reaction, and when they were slaughtered recently unmistakable lesions of tuberculosis were found.

113. **Public Health Matters in Japan.**—Dr. Yamane, a member of the house of representatives, proclaimed, in a recent debate, that more than 130,000 persons succumb annually to tuberculosis in Japan, and the number is constantly increasing. In regard to leprosy he stated: "There is no country in the world in which this disease is so prevalent and so neglected. The home office returns show that there are 33,059 lepers in Japan, while their offspring number 999,300. The authorities allow leprous beggars to sit on the public streets and to infect the very air with their spittle. . . . A very small percentage are taken into the charitable asylums under French or English management." He also referred to the fact that there are 880,000 trachoma patients in Japan, and that in Tohoku district it is impossible to obtain the requisite number of recruits for the army if some sufferers from this disease are not admitted, adding, "The Japanese army will physically collapse if things are to go on in this manner." In conclusion he raised the question as to whether the prophylactic injections of anticholera serum should be continued, claiming that they had proved practically a failure last year.

PROTOZOA AND DISEASE. By J. Jackson Clarke, M.B. Lond. Cloth. Pp. 177. Price, $2.50 net. New York: Wm. Wood & Co. 1903.

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, July 11:

Rhoads, Thomas L., first lieut. and asst.-surgeon, will proceed to Hot Springs, Ark., and report in person to the commanding officer of the Army and Navy General Hospital for treatment, and when in the opinion of the commanding officer of the hospital he has sufficiently recovered, he will return to his proper station at the U. S. General Hospital, San Francisco, Cal.

Richardson, George H., first lieut. and asst.-surgeon, will proceed to Fort Bayard and report at the U. S. General Hospital for temporary duty during the absence of Capt. George M. Wells, asst.-surgeon, and on the return of Capt. Wells to duty will rejoin his proper station at Fort Logan.

Spilman, R. S., contract surgeon, is granted leave for one month from about June 25.

Truby, Willard F., first lieut. and asst.-surgeon, now on temporary duty at Fort Ethan Allen, is assigned to permanent duty at that post.

Tenney, E. R., contract surgeon, is granted leave of absence for one month.

Woods, Oscar W., contract surgeon, now under treatment at the U. S. General Hospital, Presidio, is relieved from further duty in the Division of the Philippines, and will proceed to Vancouver Barracks and report to the commanding general, Department of the Columbia, for assignment to duty.

Arthur, William H., major, surgeon, is granted leave for six days.

Brown, Henry D., contract surgeon, is relieved from duty in the Division of the Philippines and from temporary duty at the Presidio for assignment to duty with the Second Battalion of the 19th Inf., and to accompany that battalion to Vancouver Barracks, where he will report to the commanding general, Department of the Columbia, for assignment to duty.

Borden, William C., major, surgeon, is granted leave for one month and fifteen days, to take effect about July 17.

Corbusier, William H., major, surgeon, is relieved from duty at Fort Crook, to take effect at such time as will enable him to proceed to San Francisco, Cal., and report for transportation to the Philippine Islands on the transport to sail from San Francisco August 1. On his arrival at Manila Major Corbusier will report to the commanding general, Division of the Philippines, for assignment to duty.

Duval, Douglas F., first lieut. and asst.-surgeon, will report to Maj. Louis A. La Garde, surgeon, president of the examining board at the Army Medical Museum Building, Washington, D. C., for professional examination and physical re-examination for promotion.

Devereux, John R., first lieut. and asst.-surgeon, is relieved from further duty at Fort Snelling and will proceed to Fort Meade for duty, to relieve Maj. Frank R. Keefer, surgeon, in time to enable him to comply with his orders for the Philippine Islands.

Foster, Chas. L., contract surgeon, now in Washington, D. C., will proceed to Fort Myer for duty.

Gandy, Charles M., major, surgeon, is relieved from duty in the Division of the Philippines, to take effect at such time as will enable him to proceed on the first transport to sail after September 1 from Manila to San Francisco, Cal., where he will report by telegraph to the adjustant-general of the Army for further orders.

Henderson, Albert B., first lieut. and asst.-surgeon, is granted leave for one month and ten days on surgeon's certificate, to take effect about July 10.

Keefer, Frank R., major, surgeon, is relieved from duty at Fort Meade, to take effect at such time as will enable him to proceed to San Francisco, Cal., and report for transportation to the Philippine Islands on the transport to sail from San Francisco September 1. On his arrival at Manila Maj. Keefer will report to the commanding general, Division of the Philippines, for assignment to duty.

La Garde, Louis A., major, surgeon, is granted leave for one month, with permission to apply for an extension of three months, to take effect about July 15.

Mason, Chas. F., major, surgeon, is granted seven days' leave, to take effect on the adjournment of the board of medical officers.

Marrow, Chas. E., first lieut. and asst.-surgeon, is relieved from further duty at Fort Sheridan and will proceed to Fort Crook for temporary duty.

Polhemus, Adrian S., major, surgeon, is relieved from duty in the Division of the Philippines, to take effect at such time as will enable him to proceed on the first transport to sail after September 1 from Manila to San Francisco, Cal., where he will report by telegraph to the adjutant-general of the Army for further orders.

Rutherford, Henry H., first lieut. and asst.-surgeon, is relieved from further duty at the U. S. General Hospital, Presidio, and will proceed to Fort Mackenzie for duty.

Williamson, Llewellyn P., first lieut. and asst.-surgeon, is relieved from further duty at Jefferson Barracks and will proceed to San Francisco, Cal., and report for assignment to temporary duty at the U. S. General Hospital, Presidio of San Francisco, Cal.

Winter, Francis A., captain and asst.-surgeon, is granted leave for ten days with permission to apply for an extension of twenty days.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending July 11, 1903:

Asst.-Surgeon R. L. Sutton detached from Naval Hospital, Washington, D. C., and ordered to Baltimore, Md., for special temporary duty.

Asst.-Surgeon O. Kohlhase ordered to Naval Hospital, Mare Island, Cal.

Asst.-Surgeon W. H. Rennie ordered to Naval Hospital, Naval Home, Philadelphia, Pa.

Asst.-Surgeon W. B. Smith ordered to Naval Hospital, Pensacola, Fla.

Asst.-Surgeons J. S. Woodward and P. T. Dessez ordered to Naval Hospital, Navy Yard, Washington.

Asst.-Surgeon J. D. Manchester ordered to Naval Hospital, Navy Yard, Boston, Mass.

Asst.-Surgeons A. J. Geiger and W. S. Haen ordered to Naval Hospital, Navy Yard, Norfolk, Va.

Asst.-Surgeons C. E. Ryder and J. A. Randall appointed asst.-surgeons with rank of lieutenant, junior grade, from June 26, 1903.

Acting Asst.-Surgeon J. T. Miller ordered to Navy Yard, Mare Island, Cal.

Acting Asst.-Surgeon F. W. Tyree appointed acting asst.-surgeon with rank of lieutenant, junior grade, from July 1, 1903.

Medical Inspector S. H. Dickson granted sick leave for three months.

Acting Asst.-Surgeon G. R. Plummer appointed acting asst.-surgeon with rank of lieutenant, junior grade, from July 1, 1903.

Surgeon H. N. T. Harris detached from *Glacier* and ordered home to wait orders.

Surgeon F. W. F. Wieber detached from Naval Academy and ordered to wait orders.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended July 9, 1903:

Surgeon J. M. Gassaway granted leave of absence for two days from June 28, amended so as to be effective from July 5.

Surgeon G. W. Stoner to proceed to Richford, Vt.; Malone, Niagara Falls and Buffalo, N. Y.; Montreal, Canada; Port Huron, Detroit, and Sault Ste. Marie, Mich., for special temporary duty.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence, on account of sickness, until July 15.

Asst.-Surgeon F. E. Trotter, granted leave of absence for 7 days.

Asst.-Surgeon A. J. McLaughlin, assigned in charge of Miscellaneous Division, Bureau of Public Health and Marine-Hospital Service.

Asst.-Surgeon H. McG. Robertson, granted leave of absence for 5 days.

Acting Asst.-Surgeon R. Chandler, granted leave of absence for 8 days from July 18.

Acting Asst.-Surgeon F. H. Cleaves, granted leave of absence for 23 days from July 6.

Acting Asst.-Surgeon R. S. Primrose, granted leave of absence for 10 days.

Acting Asst.-Surgeon W. M. Wightman, granted extension of leave of absence for one week from June 26.

BOARD CONVENED.

Board convened to meet at Washington, D. C., July 8, 1903, for the purpose of considering the preparation of plans for the inspection of vaccine farms and antitoxin establishments. Detail for the board: Asst. Surgeon-General H. D. Geddings, chairman; P. A. Surgeon M. J. Rosenau; P. A. Surgeon J. F. Anderson, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended July 11, 1903:

SMALLPOX—UNITED STATES.

California: Fresno, June 1-30, 7 cases; Stockton, 4 cases.
Colorado: Denver, June 6-20, 15 cases.
Georgia: Atlanta, June 24-July 1, 2 cases.
Illinois: Belleville, June 27-July 4, 6 cases; Chicago, 11 cases.
Indiana: Elwood, June 28-July 5, 3 cases.
Iowa: Des Moines, June 27-July 4, 3 cases.
Kentucky: Lexington, June 27-July 4, 1 case.
Louisiana: New Orleans, June 27-July 4, 1 case.
Maryland: Baltimore, June 27-July 4, 1 case; Cumberland, May 1-June 30, 45 cases, 6 deaths.
Massachusetts: Fall River, June 27-July 4, 1 case; New Bedford, June 29-July 6, 1 case.
Michigan: Detroit, June 27-July 4, 5 cases, 1 death; Flint, 1 case; Grand Rapids, 1 case; Port Huron, 5 cases.
Minnesota: Winona, June 27-July 4, 1 case.
Missouri: St. Louis, June 21-July 5, 7 cases.
Montana: Helena, June 1-30, 1 case.
New Hampshire: Manchester, June 27-July 4, 7 cases.
New York: Elmira, June 27-July 4, 1 case.
Ohio: Hamilton, June 27-July 4, 1 case; Toledo, 1 case.
Pennsylvania: McKeesport, June 27-July 4, 2 cases; Philadelphia, June 26-July 3, 30 cases, 8 deaths; Pittsburg, June 20, July 4, 46 cases, 9 deaths, two cases imported.
South Carolina: Charleston, June 27-July 4, 8 cases; Greenville, June 20-27, 1 case.
Tennessee: Nashville, June 27-July 4, 1 case.
Utah: Salt Lake City, June 21-27, 7 cases.
Washington: Tacoma, June 22-29, 1 case.

SMALLPOX—INSULAR.

Philippine Islands: Manila, May 8-16, 6 cases.

SMALLPOX—FOREIGN.

Belgium: Brussels, June 13-20, 7 deaths; Liege, June 6-13, 1 case, 1 death.
Brazil: Rio de Janeiro, May 31-June 14, 12 deaths.
Canary Islands: Las Palmas, June 6-13, 9 cases.
Chile: Antofogasta, May 1-31, 3 deaths.
China: Hongkong, May 20-27, 2 cases.
Colombia: Bocas del Toro, June 17-24, 2 deaths.
Great Britain: Birmingham, June 13-20, 1 case; Dublin, 9 cases, 3 deaths; Leeds, June 20-27, 10 cases; Liverpool, to June 20, 24 cases, 2 deaths; London, June 13-20, 16 cases; Manchester, 3 cases, 1 death.
India: Bombay, June 2-9, 24 deaths; Calcutta, May 30-June 6, 2 deaths; Karachi, May 30-June 7, 1 death.
Mexico: Coatzacoalcos, June 20-27, 1 case; Tampico, 1 death.
Russia: Moscow, June 6-13, 3 cases, 2 deaths; St. Petersburg, June 13-20, 35 cases, 2 deaths; Warsaw, May 31-June 6, 6 cases.
Turkey: Constantinople: June 14-21, 1 death.

YELLOW FEVER.

Alabama: Mobile, July 3, 1 case on S. S. *Mount Vernon*, from Limon. July 4 death of case occurred at Gulf Quarantine, Ship Island.

YELLOW FEVER—FOREIGN.

Ecuador: Guayaquil, June 6-13, 1 death.
Mexico: Progreso, June 20-27, 1 case; Tampico, June 13-20, 37 cases, 23 deaths; Tampico, June 20-27, 30 deaths; Vera Cruz, 20 cases, 8 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, May 8-16, 66 cases, 58 deaths; Provinces, 358 cases, 245 deaths.

CHOLERA—FOREIGN.

India: Bombay, June 2-9, 1 death; Calcutta, May 30-June 6, 35 deaths; Karachi, May 31-June 7, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, May 8-16, 8 cases, 8 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, May 10-16, 6 cases.
China: Amoy, May 9, 50 deaths; Two Kwangs, May 12, daily increasing.
India: Bombay, June 2-9, 229 deaths; Calcutta, May 30-June 6, 11 deaths; Karachi, May 31-June 7, 43 cases, 35 deaths.
Japan: Nagasaki, May 21-31, 1 case, 1 death; Yokohama, May 23-30, 3 cases, 3 deaths.

THE ILL-HEALTH OF RICHARD WAGNER.

GEORGE M. GOULD, M.D.
PHILADELPHIA.

The following quotations are from the life by Glasenapp and Ellis, and from the volumes of letters to Heckel, Wesedonck and Liszt. I regret exceedingly that the reproduction here of so large a number of excerpts is necessary. I have omitted many that seemed possible to be spared and not spoil the clinical picture. Only by the careful reading can one get a clear idea of Wagner's sufferings and symptoms, and be thus enabled to come to a sound diagnosis of the one malady that resulted in such various and life-long symptoms.

RICHARD WAGNER [Lenbach].*

Richard Wagner was born in 1813. His delicate constitution required peculiar care, for he was already troubled with that irritating form of erysipelas (erythema or eczema?) which recurred at intervals throughout life . . . Down to his sixth year he had no regular lessons; the mother wished to give him time to pick up strength, and would not have plagued him with school work. . . . A pale, slim little chap in short-armed frocks, but unruly enough already—thus the traditions show the tiny Richard. G., p. 61.

My good uncle tried his best to put me through some educational training, . . . That I did not profit much by his instruction was, I fear, my own fault. I preferred rambling about the little country town and its environs to learning the rules of grammar. . . . I often beguiled my uncle into reading me a story that I might avoid working. 1821 or 1822.

By right they had to suffer for each other, as both were most excitable and fitful sleepers. . . . Cäcilie had plenty to say of her brother's sudden shouts and talking in his sleep, his laughter and tears in the night. 1822-1823.

To roam about the country was his chief delight. *Do.*

He ranked among the best pupils in that gymnasium from the first, and passed through various divisions and classes with fair rapidity. 1822-1827.

He was plagued with a cutaneous malady even in his school days. . . . Repeated attacks of the kind . . . An attack would be preceded by depression of spirits and irritability of temper. Conscious of his growing peevishness, he would seek refuge in solitude. As soon as the attack was subdued, his bright animal spirits returned. *Do.*

The refinement and energy of his features and the look of wanness and suffering they wore. About 1838.

The prose must be turned into verse, and the music composed in a fortnight. . . . his nerves have been so overtaxed that he has "often sat down and wept for a quarter of an hour at a stretch." 1843.

Constant victimage to a feeble stomach while instrumenting Tannhäuser in 1845.

My whole being had been so consumed with ardor for my task that the nearer I approached its completion the more I was haunted by the notion that a sudden death would stay my hand; so that when at last I wrote its closing chord I felt as joyful as if I had escaped some mortal danger. 1845.

Lonely walks. 1845.

Devoted some five weeks from July 3 to humoring his health, as well as his unresting brain would let him. 1845.

Despite the doctor's warnings against my engaging in any such occupation. Working at Lohengrin, 1845. The doctor's orders were so emphatic against any interruption of his present cure that Wagner was obliged to abandon the outing. . . . The reason for declining was a determination of blood to the brain, brought on by his exertions of the past season, not yet left him. *Do.*

Scarcely could he himself say for certain whether his state of health was the cause of his low spirits or they the ground of his feeling so unwell; perhaps it was a little of both. 1846.

The condition of his health just now is proved by his obtaining a three months' leave of absence, "to breathe again as man and artist" in Switzerland. 1846.

Indulged in his favorite pastime, reading. 1846.

*By the courtesy of Dent & Co., the publishers of Chamberlain's "Richard Wagner."

Was there any possible way out—save death? 1847.

He speaks of a sick bed to which he has been confined for some days. The indisposition must have lasted for at least a month, for in January, 1848, he wrote that he has had a "severe attack of illness." 1847-1848.

He was busy with ideas for a big work from German mythology, but feared he might be too old, and should have undertaken it when younger. 1848—aged 35.

The writing of the Niebelungen Myth is followed by "a period of great depression." 1848.

Winter seems to have been always attended with a certain lowering of vitality. Last year we saw it take the form of a serious illness; this year it takes that of a general depression of spirits. . . He felt "too old" to undertake his Siegfried. 1848-1849.

The sole redemption lay in flight from out this life, in casting off its claims on me by self-destruction. End of 1848.

Gnawing torments. 1848.

His passport describes him as "of medium stature, brown hair, wears glasses." 1849.

His ancient winter foes return, particularly rheumatism, which this time makes an inroad on his heart. 1849.

He was thoroughly broken down for the present, what with rheumatism and his recent spell of literary work at high pressure. January, 1850.

Feeble, full of pain, unable to sleep, in search of quiet. February, 1850.

I'm happy to tell you I've got to the root of my illness; a violence done to my spirit had aggravated my bodily torments to a dangerous pitch. February, 1850.

He means to take a journey southwards for complete recovery of his health. March, 1850.

RICHARD WAGNER.*

I've lost my health, my nerves are shattered. For the present I can live for little more than convalescence. . . . My sufferings became so insupportable that the instinct of life drove me to save myself by breaking with everyone . . . and fleeing into God-knows-what strange land. 1850.

Ah, let us above all things get health. 1850.

Ill, very ill as I was. Letter to Heine, 1850.

Four to five months were indeed too short to devote to a work of such originality and magnitude; too short for the author's own health . . . The last pages of this copy I have written in a mood I can intelligently describe to no one. Candidly speaking, my only wish is to get the hateful manuscript out of the house. Of "Opera and Drama." 1850.

Nine years afterwards Wagner refers to the "fatigue" that had come over him when writing "Opera and Drama," a fatigue that "so sorely weighed upon his brain" that he calls it an "abnormal state of mind." *Do.*

I am glad to be able to tell you that I have discovered the nature of my illness; it was to a great extent melancholy; at any rate, a strained state of mind has brought my constitution into the present dangerous and excited condition. 1850.

My illness was the result of melancholy. 1850.

The master has just been ordered to the water cure. 1851.

His health was so broken by previous excess of work. 1851.

Winter is my mortal enemy. 1851.

My headlong mode of working always tells upon me somewhat severely in the end, and I am obliged to recuperate awhile, as usual; for the next few days, accordingly, I can not undertake the making of a copy for you. 1851.

To my joy I found music shaping itself to these verses most naturally and easily, altogether of itself as it were. Only the first beginning of this labor warned me that I should completely undermine my health, if without having thoroughly attended to it, I yielded to my impulse, and pursued—presumably without a break—what I had just begun. So I came to this hydropathic establishment. 1851.

Had I gone to my "young Siegfried" in my present state perhaps I should have become incurable by next spring. Moreover, if I had dragged along with my infirm lower man I should have been highly inconsistent with my principles. The idea of setting to work at my Siegfried in perfect health has something of what I might call a glad solemnity. So — it's settled — I shall undergo the complete water cure. 1851.

I have become a complete water man. This time I was ten weeks in the hydropathic establishment; only on account of the winter setting in early and with great severity have I given up the cure for the present. However, it was sufficient to give me the clearest foretaste of perfect health, a new and indescribable feeling of comfort, etc. 1851.

This "water" interlude we may take as a not unwelcome relief in the midst of a more intricate topic. What Wagner had to undergo, however, in the vain attempt to diet his body into a condition of robust health, would be past belief in these days of saner physiology had we not his written word for it. Poor Uhlig himself, its original instigator, succumbed to the effects of a less drastic form soon afterward.

It was nearly a twelvemonth since that Uhlig began pressing his "water views" on his leader; Wagner then replied, "I only drink water when I feel a thirst for it; yet I am far less sanguine than you!" (Oct. 9, 1850.) But the idea soon exercised a kind of fascination over him; in a fortnight he is so far on the road to conversion that he admits its value on the testimony of his younger friend's experience. By Christmas he had commenced to experiment on himself, in an amateur fashion: "I, also, am doing a sort of water cure; besides a sponge down in the morning, cold water drunk in bed." That does

*Reproduced from Chamberlain's "Richard Wagner," by the courtesy of Dent & Co.

not satisfy the zealot Uhlig; he recommends a "Neptune girdle," which sounds something like a wet waistband, and makes one shiver at the thought of wintery cold in Switzerland. Wagner valiantly attempts it. "I followed your advice about the Neptune girdle at once. I hope it will suit me. On the whole I feel surprisingly better than last year." (Jan. 20, 1851.) Two weeks later, however, he has paid the penalty of dabbling. "I'm rather unwell. By the advice of a first-rate physician, who also is an advocate of water, I have had to lay aside the Neptune girdle for a time." And laid aside it appears to have remained, till Uhlig came to Zurich and waxed eloquent about the virtues of a system that decidedly had added neither color to his cheeks nor flesh to his bones.

Uhlig unluckily did more; he brought with him a water volume by a certain Rausse, and well-meaningly left it behind him. On the 24th of August (1851), taking a rest after the labor of fair copying the Communication, Wagner relates how he has begun to turn Rausse's theories into practice during the past week: no wine, no beer, no coffee, no soup; only cold water and milk, so far as drinkables are concerned; 3 to 4 glasses of cold water in bed before rising, and any number of glasses during the day; baths at home, or in the lake at midday; half an hour's walk immediately (!) after food. No wonder he remarks that his head feels "lighter, but often somewhat dull," though he considers the latter a mere passing effect, and expects "to end by getting more health than I shall know what to do with." Naturally the end of another fortnight reveals him in a wretched state, so wretched that he has been to consult the proprietor of a hydropathic quackery (September 8), who equally naturally insists on his coming there, to submit to heroic measures. September 16 Wagner goes to Albisbrunn in the commune of Hausen, on the hills to the southwest of Zurich, too ill to think of any Siegfrieds for the moment.

RICHARD WAGNER.

From Rubenstein's arrangement of the vocal score of Tannhäuser. This photograph probably formed the basis of Lenbach's realistic drawing.

On the whole, these ten weeks at Albisbrunn appear to have done him temporary good, but rather as a change of air and scene, a relaxation of mental strain, than in any other way. His humor does not forsake him, and it is here that his gigantic plan matures; but when one reads of the treatment to which he is subjected, one can feel nothing save amazement at the power of resistance innate in his constitution. This is how he describes the "cure," a fortnight ere its termination: "My daily program now: 1. From 5:30 to 7 in the morning, cold pack; then cold tub. Wanne and promenade; breakfast at 8, dry bread and milk or water (no butter allowed, as he says in another letter). 2. Short promenade again; then a cold compress. 3. Towards 12 o'clock a wet rub-down; short promenade; another compress. Then dinner in my room, to avoid disrelish (was it, or the sight of other victims, so nasty?). An hour of idling; brisk walk of two hours—alone. 4. About 5 o'clock another wet rub-down and a little promenade. 5. Hip bath for a quarter of an hour, about 6, followed by a promenade to warm me (surely in a corridor, for it must have been pitch dark by then). Another compress. At 7, supper; dry bread and water. 6. Whist party till 9, followed by another compress; and about 10 o'clock to bed. This regimen I now can manage very well; perhaps I shall even increase it." "I feel myself on the high road to recovery." 1851.

Quiet! Quiet! Quiet! Country! Country! Then—health—cheerfulness—hope! else—all is lost! I can no more. 1851.

Beyond the water business my employment consists in building a house on paper with rule and compass. 1851.

This winter I shall idle for my health, only sketching as thoughts occur to me. 1851.

For the recovery of my youth, for health, nature, an unreservedly loving wife and a flock of children I would barter *all my art!* There, take it! Give me the other. January, 1852.

I have got so far that I place no faith in any system, but only in a specially gifted and sound physician, an individual. For such an one I long, not for any fads. 1852.

The water cure had "worked wonders," as he fondly imagined for a while. "I am basking in a sense of a well-being such as I had never conceived. My indomitable cheerfulness," etc.

At Albisbrunn he had been condemned in the end to baths of but 7 degrees above freezing point; at home he has raised their temperature to the more civilized limit of 55 F., but mental rest is strictly enjoined on him, together with a diet which he describes as "dry bread" and milk for breakfast, dry bread and water for supper; at midday English cooking, i. e., vegetables boiled plain and meat roasted on the spit . . . The water business he still has so at heart that he writes to Sulzer a defense of it three quarto pages long, though the only extract published by Herr Steiner does not make clear whether outward or internal application is the bone of contention: "As I could not possibly subside into a merely casual acquaintance with a man who has been and is, at a crucial period of my life, what you have been and still are to me; a man I sincerely respect in the warmest sense of which that word is capable—the ultimate consequence (of Sulzer's recusance) would be that I must give my Zurich haven up; a necessity I feel so deeply that I was compelled to declare it yesterday to our two friends." It is difficult to believe that such earnestness has reference to nothing more serious than a divergence of views on the efficacy of water; but, however we interpret it, Herr Steiner further informs us that, rather than allow the split to go to such a length, Sulzer made certain "concessions."

As for Wagner himself, departure from a strict observance of cold water soon was forced on him by the same consideration that had started it—his health. All through this winter, in fact until next autumn, we hear of one modification or another, in the endeavor to restore a shattered set of nerves, culminating in the lesson of experience passed on to Uhlig next October: "Our water doctors, one and all, don't know enough about nerve troubles. Constitutions like mine are benefited by none but warm baths, whereas cold ones ruin them entirely. If I can only get my nerves right, you'll hear another story!" The same with his teetotalism, which is wisely abandoned at last for an occasional glass of good wine. Had he but had his good Dresden doctor Pusinelli within arm's length, instead of various experimenters on a bodily constitution they understood as little as his critics his artistic theories, perhaps the music of the Niebelungen might have actually been finished in not much over the three years orig-

inally propounded for its term. But the awl of the amateur health cobbler was picked up first by one friend, then by another, till the letter last quoted avows: "For the present my doctor is Herwegh: he has great knowledge of physics and physiology, and is more sympathetic toward me, in every respect, than any physician who is not at the same time a friend." February, 1852.

"I'm terribly fatigued again." March, 1851.

I am daily thinking of my death. 1852.

I can not pull round as yet, and am suffering from sleeplessness with great dejection. *Do.*

Beethoven, the Holländer, ill health, sleepless nights, repeated disillusions—all were factors in the evolution of that colossal drama which had occupied his brain ever since he returned from Albisbrunn. G., 1852.

I am now living for nothing but my health. I am taking a rest after the somewhat trying effects of my late cure. Dec. 14, 1851.

It is to no water establishment that Wagner goes this time, as once proposed; his faith in that drastic regimen has been rudely shaken during the last few months. Moreover, "it is quite impossible for me to spend half a year at a hydro." Not long ago he had heard through Ernst Kietz of a certain Dr. Karl Lindemann, a fellow exile, then "working remarkable cures in Paris with a marvellously mild water régime. His specialty seems to be nervous disorders." So he had written Lindemann a detailed account of his symptoms, and received a regular chart of instructions to cover a protracted period: for diet, chiefly game simply cooked, with a glass or two of good wine; his baths to be tepid rather than cold; the main affair—"I'm to keep quiet and write poetry." May, 1852.

The open air is doing me much good; every morning I roam about for two or three hours before setting to work. My working time I don't extend beyond two hours a day; it was by frequently working five to six hours that taxed my nerves before. I have finished the entire draft of the Walküre now. May, 1852.

His lonely walks. *Do.*

Yesterday I finished my Walküre after a month of work. . . . once more I am somewhat severely knocked up; no doubt I work at too high pressure. July 2, 1852.

When I've finished a thing like the Walküre I always feel as if I had sweated a huge anxiety out of me, an anxiety ever increasing toward the end of the work, a kind of dread lest I should spoil something: my signature and date foot the page, as though the devil were standing behind me, trying to stop my last stroke. Much the same had it been with the scoring of Tannhäuser: The nearer I approached its completion the more I was haunted by the notion that a sudden death would stay my hand; only there is a new element here. *"Lest I should spoil something."*

I was going to begin the composition and found to my joy that the music adapted itself to these verses quite naturally and easily, as if of its own accord. But the very commencement of the work reminded me that I should ruin my health entirely if I did not take care of it thoroughly before yielding to my impulse and finishing the work at a stretch and probably without interruption. When I went to the hydropathic establishment, etc. (November, 1851. Letter to Liszt.)

My previous continual anxiety about my health has also now been relieved by the conviction I have since gained of the all-healing power of water and of Nature's medicine; I am in the way of becoming, and if I choose, of remaining, a perfectly healthy man. If you wretched people would only get a good digestion, you would find that life suddenly assumes a very different appearance from what you saw through the medium of your digestive troubles. (November, 1851. Letter to Liszt.)

I am still occupied in resting from the finally somewhat powerful effect of my cure. December, 1851.

We sedentary animals scarcely deserve to be called men. How many things we might enjoy if we did not always sacrifice them to that damnable "organ of sitting still." 1852.

The nerves of my brain are so overwrought that even these few lines set me in a violent commotion. I find that I may be able to do something good, but only on condition that I keep a strict watch on myself, and especially that I interrupt my work often and completely divert my thought before going on again. May, 1852.

Then I had a sublime view of the terrible mountain world of ice and snow and glacier, which seems to be so close that one might clutch it—I am walking capitally, quite strong on my legs; only I'm not contented with my head as yet. The nerves of my brain are hideously out of order; agitation or prostration—never any time true repose. July, 1852.

My digestion has been in a very bad way of late. *Do.*

Peace I did not find. It's all up; there's no youth left in me; to live stands no longer before me; all my making and doing can now be naught but gradual decay. The nerves of my brain, there's the trouble. *Do.*

Unfortunately I can work but slowly, as everything is an uncommon tax on my brain just now. Only to-day have I finished the MS. of my address on the performing of Tannhäuser. . . It has taken much out of me, and I shall have to try to rest it off. August, 1852.

Throughout the whole of these six months we hear one constantly repeated cry of "headache," as if the twofold strain on the mind were wearing out its organ. At no other period does the physical suffering appear to have been at once so acute and so protracted. Is it a condition normally attendant on the birth of a colossal masterpiece? "My health is none of the best, and although my body looks fairly robust, my nervous system is in a serious state of increasing exhaustion. Through this everlasting life of phantasy without any corresponding reality, the nerves of my brain are so severely overwrought that I can only work by spurts now, and with long interruptions, if I don't mean to become a complete and chronic wreck." *Do.*

From the perpetual expression "the nerves of my brain" ("meine Gehirnnerven"), coupled with the apparent "robustness of body," I should argue (writes Ellis) that the malady was nothing deeper-seated than megrim, alias migraine or "sick headache"; but anyone who has ever been a victim to that scourge, similar in many of its nervous symptoms to "influenza," will recognize the sheer impossibility of mental application when an attack is in full swing. The various forms of dieting to which Wagner had subjected himself would only tend to lower the general tone of the nerves, and thus exacerbate the malady; whereas the last thing a sensible physician would have advised would have been the climbing of dizzy Alps and the forced march across the Italian frontier, which the patient had undertaken on his own account by way of recuperation. And on his holiday to be plagued with business details, too! The result is, that he returns to Zurich so prostrated that he exclaims to Uhlig a day or two after: "You people mustn't talk theory any more to me just now; it sends me clean crazy. The nerves of my brain! there's the mischief. I've terribly assaulted them; it's quite possible I may yet go mad!" August 9, 1852.

And so it goes on, with variations of the same complaint (chiefly addressed to Uhlig), at least until the Rheingold poem is completed and the greatest load thus discharged from his mind. At first, in fact, it is impossible even to think of poetry. "I've written Heine to-day. My head is not yet clear enough for working." August 11.

"Unfortunately I'm getting on very slowly (with the Tannhäuser Guidel), as all manner of work tries my head uncommonly just now." August 14.

"If my head were but better! With that cursed brochure, which I rushed at last so as to polish everything off, I ruined myself again. Often it's like a sharp knife cutting into the nerves of my brain. Moreover, I'm feverishly tired in all my limbs; but if only my head will recover, they also will rapidly improve; on it—that laboratory of the imagination—depends everything. . . . Forgive me my many commissions; but if you don't do a double turn for me now, 'twill be all up with

me. Think of it! even this letter almost knocks me down." August 30.

There cause and effect are plain as can be; the Tannhäuser, with all the correspondence involved, has told severely on an excitable system, and the "nerves of his brain"—scientifically speaking, the region round about the optic thalami—must pay the penalty. That "sharp knife" cutting, the "feverish tiredness in the limbs," and the sense of impending evil, are the very symptoms of megrim; the attacks of which, especially if brought on by mental labor, may sometimes be prolonged for several days by successive relapses.

"Only two lines; I mustn't write, because I can't; that's how things stand with me"; and after barely a dozen lines, "I can write no more. Good-bye." Three days later an equally short letter, so unusual in this correspondence, ends with "That's all I'm able to squeeze out to-day. Don't take it amiss!" September 8.

On the same date that notable letter to Liszt about Raff, Berlioz and new creations (p. 360 ant.), begins and ends as follows: "Unluckily I can't reply to you as I should wish. The nerves of my brain are so racked again that I have had to give up all writing and reading for a while—I might almost say, all mental existence. Every letter—even the briefest—knocks me terribly up, and nothing save the greatest quiet (where and when?) can—or rather, could—put me really right. . . . I can write no more now! Don't be cross with me! My head is nigh bursting! I'll just hurriedly add the warmest farewell I have in my heart." Another three days later: "My head is still bad, and all my nerves upset, in consequence of this eternal friction with an invisible load outside. . . . Farewell, I must stretch myself full length on the divan, to close my eyes (to U., September 11).[1] Next day we have the letter to Roeckel, cited a page or two back. A week after that: "I am growing accustomed to the ruin of my nerves; one can always do a little something with them still. . . . To-day is the federal fast day, and for the last week the Föhn has been enough to make one wish one's nerves at the Devil." The Föhn is a moisture-laden south wind peculiar to the valleys and lakes of Switzerland, but similar in its general effects to the sirocco so prevalent at Venice, etc. Its humidity would really seem to have eased the writer, however, much as a vapor bath might; for, not only does he indulge once more in a good streak of his pristine humor in this letter of September 19 to Uhlig, but also has important news for us: "My condition isn't a hair's breadth better yet; only I'm gradually accustoming myself to a fresh degradation of my health; I'm accommodating myself to it, and even work a little hour a day now!"

Progress with the poem was by no means break-neck at first: "a little hour a day." Nor even every day; for a fortnight later the intimation to Liszt runs, "My nerves are still none of the best; yet I have begun to work a short hour a day at my poem again, off and on. There'll be no peace for me till I know it is finished, which I hope will be ere long." October 3.

The presence of Belloni and Vieuxtemps would scarcely expedite matters, and October 5 we read (to U.), "I shall tell you nothing about my work; it's going slowly, but well!" Unhappily the next sentence is ominous: "Farewell and healthier than me. I shall shortly go crazy!"—a repetition of the fear expressed two months ago. Before a week is out the poem has to be laid aside: "That I am able to write you at all to-day is simply due to my decision to make a forced pause in my poetic work, not to fall once more into that fatal condition the most painful effects of which I have only just outrun a little. Letter-writing, however, I now am convinced once for all severely taxes me, and you therefore may flatter yourself if I manage even to fill this sheet of paper. If the weather were not so inveterately bad I should have started to-day on a couple of days' excursion. Already I had mapped out a tour to Glarus and Schwyz. Unfortunately, with this eternal gray dampness of the atmosphere I shall have to adjure any pleasure trip; simply my afternoon walk I keep up, mostly three to four hours, however hard it rains, albeit with a hang-dog sort of pleasure." October 11.

The "sheet" gets filled to overflowing, nevertheless, and lower down this letter we learn that "warm baths of 86 degrees for half an hour in the evening just before going to bed" have helped him much. "Without that bath I should have been a lost man by now; it quiets my nerves and gives me good sleep every time. Lindemann has even advised me to take a similar bath for half an hour in the morning, if I want to get rapidly well; for the present I only take a short one in water chilled to 77 degrees. My head I repeatedly douche with colder water during each bath." It is while thus "comparing notes" with a brother invalid, poor Uhlig, that Wagner receives the elating news of the Breslau success of Tannhäuser.

(To be continued.)

1. Under the heading "Megrim (migraine, hemicrania, sick-headache), a standard English medical authority remarks: "During the paroxysms nothing is so efficacious as complete rest in the recumbent posture, in a perfectly quiet and darkened room." The further statement that his malady "generally subsides with advance of years. Patients do not often suffer from it after 50," bears out my diagnosis, since we do not hear of these sick headaches when Wagner has passed that age.—W. A. E.

EPISPADIAS.

REPORT OF A CASE OPERATED ON BY A MODIFICATION OF CANTWELL'S METHOD.*

JAMES B. BULLITT, M.D.
LOUISVILLE, KY.

The purpose of this paper is to again call attention very briefly to an almost ideal operation for the relatively rare but distressing deformity, epispadias; and, further, to describe a modification of the original operation which the writer found it necessary to make in the single case on which he had the opportunity of operating.

This operation, described by Cantwell[1] in 1895, performed by Herbert Page,[2] in 1898, and again by Parham and Martin[2] in 1900, seems not to have gained the recognition it deserves, and not to have found its way into the recent text-books of surgery.

Bryant voices the sentiment of practically all the text-book writers when he says: "The ability to secure as satisfactory results in this deformity as have been secured in hypospadias has not yet been attained."

The procedures usually recommended are similar to the plastic operations applicable to the condition of hypospadias, and of these the methods of Thiersch and Duplay are the best and most useful examples. But these operations leave much to be desired, both from the standpoint of functional result, in overcoming the incontinence, and the length of time required for the progressive steps.

Cantwell's operation, having for its object the transplantation of the newly formed urethra to its normal situation beneath the body of the penis, permits a quick result to be obtained, and relieves entirely, or in a marked degree, the distressing incontinence.

TECHNIC BY CANTWELL.

Briefly described, the operation of Cantwell is made as follows: A curved pair of forceps is first introduced into the bladder and its point made to bulge the perineum. This is cut down on and drainage of the bladder provided by means of a rubber tube which is left in place until the process of healing is complete. Next an incision is made on both sides of the penis at the junction of the mucous membrane and the skin beginning proximally at the opening of the bladder, and extending distally to the end of the glans penis. The

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

1. Annals of Surgery, December, 1895.
2. Ibid., January, 1901.

meatus is usually just under the pubic arch. The mucous membrane lining the groove on the dorsum of the penis, and marked out by these incisions, is now dissected up, care being taken to carry the dissection well back to the infundibulum, almost to the bladder wall.

When this is thoroughly done the urethra can be drawn out surprisingly. This mucous membrane flap is now converted into a urethral tube by suturing its free edges together, and should be long enough to reach quite to the end of the glans penis.

Next a new bed for the urethra is made by dissecting apart the two cavernous bodies, leaving them attached only by the skin at the under surface of the penis. In the normal penis this separation would be most difficult, but in epispadias is extremely easy. This separation should be carried well back behind the pubic arch, so as to transplant deeply the urethra for its whole length; a slight incision is necessary in the glans. The urethra is now transplanted into this groove between the corpora cavernosa, a few sutures serving to anchor it to the underlying skin of the penis. Above the urethra the corpora cavernosa are brought together and united by continuous suture; and finally the overlying skin, which is usually abundant for the purpose, is sutured over all. This produces a penis which presents a surprisingly normal aspect, except for the apron of foreskin.

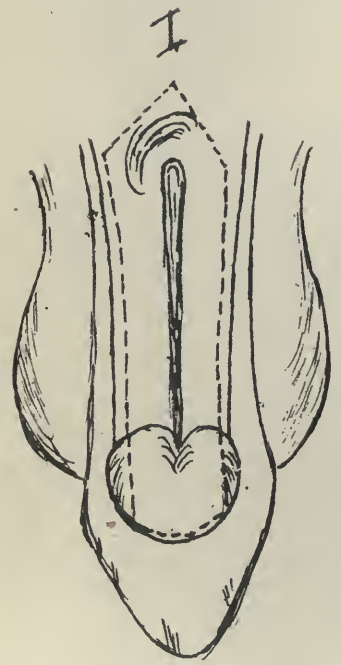

Fig. 1.—After Cantwell.

If healing occurs by first intention, the whole procedure is through with in two weeks' time. The patient is able to retain his urine almost perfectly in some cases, and can void a full stream through a meatus at the normal situation in the glans penis.

MODIFIED METHODS.

Cantwell recommended that the operation be not undertaken under 10 years of age, because of the small size of the parts and the presumption that the younger the patient the more dangerous any operation. The case reported by Parham and Martin, however, was only 5 years of age, and my own was 7 years of age. There are certainly reasons why it is advantageous to perform the operation at an earlier age than originally recommended by Cantwell. My own patient, operated on in 1901, was a boy of 7 years, otherwise healthy and well developed. The meatus was beneath the pubic arch, and the foreskin hung down in a well-marked apron. On dissecting up the mucous membrane over the sulcus and the glans penis, it was found impossible to avoid injuring this portion of the mucous membrane to such an extent that it had to be discarded and cut away entirely. As a consequence, the new made urethra was too short; even after thoroughly mobilizing it and drawing it well forward it could only be made to reach

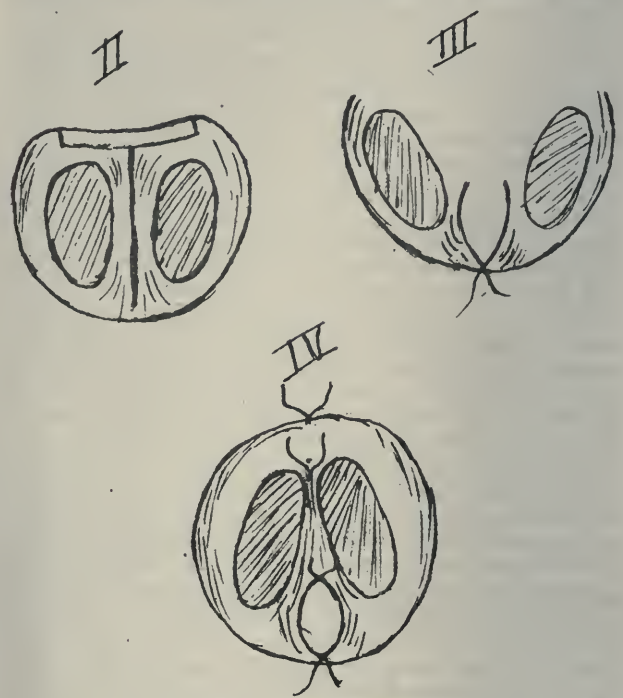

Fig. 2.—After Cantwell.

a point well behind the glans penis. It was therefore found necessary to adopt the suggestion made by Parham to combine Van Hook's method[3] of tubular canalization with Cantwell's urethral transplantation. Van Hook, in a case of hypospadias, made a canal by tunneling through the glans penis, and then lined this canal with a pedunculated flap, converted by suture into a

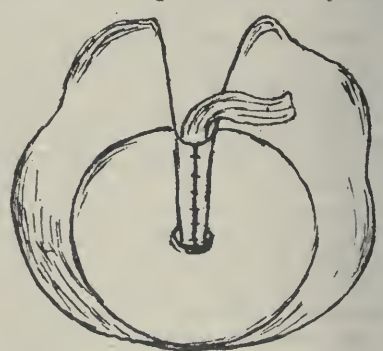

Fig. 3.—Van Hook's operation; forming preputial lining for tunnel through glans penis.

tube, taken from the preputial hood. The distal end of this flap, now become proximal, was finally sutured to the distal end of the urethra, so completing the canal.

In my case a sufficient flap was cut from the underlying preputial apron, was then converted into a tube by suture, and finally was drawn through a tunnel made through the glans penis. It was then united over a soft catheter to the already formed proximal portion of the urethra. The remaining steps of the operation were

3. Annals of Surgery, vol. xxiii.

carried out in accordance with Cantwell's recommendations. The success of the operation was surprising. With the exception of a pin-hole opening situated a little in front of the pubic arch, there was healing throughout by first intention. At the end of ten days the perineal drainage was withdrawn, and three weeks after operation the boy was exhibited to the Falls City Medical Society. He had been instructed to retain his urine for several hours before exhibition, a thing utterly impossible before operation. Just as he was placed on the table he found it impossible to longer retain his urine, and discharged several ounces over the table and carpet in a stream from a meatus situated at the end of the glans penis.

Singularly enough, I found the closure of the pin-hole fistula more difficult than the original operation. Having failed in one effort to close it, opportunity has not yet presented to successfully deal with it.

This boy's continence has markedly improved. A recent report informs me that there is occasional dribbling by day and sometimes wetting of the bed at night; but this latter is not by dribbling, but by voiding at one time a bladder full of urine.

In conclusion, I desire to say that I feel satisfied that no other operation, in my hands, could have produced anything like so good a result in anything like the short space of time.

DISCUSSION.

Dr. F. W. Parham, New Orleans—I think the condition of epispadias, although an extremely rare condition, merits our serious consideration, because when present it is so very distressing. I find myself in the singular position of making suggestions in the treatment of a condition wherein I have not had a single case to operate on. However, I have had the good fortune to assist my friend, Dr. Martin, in such a case, and I have seen another case in which Dr. Fenner has obtained a very satisfactory result by the method commended in the paper of Dr. Bullitt. The old operations of Nélaton, Rosenberger and others did not fulfill the conditions because, although they effected the re-establishment of the canal, this was too pouch-like, and the incontinence was not relieved. Beside, the time required was too long. None of the later operations have proved satisfactory, except that of Cantwell of Trenton, endorsed by Dr. Bullitt in his paper. I have looked up the subject thoroughly, and I find no procedure that can compare with it in simplicity and results. Cantwell's operation at once places the canal below the organ, where it belongs, and the whole operation can be finished at one sitting. In the normal penis the union of the corpora is very intimate, indeed, so intimate that the fibers of one side seem actually to decussate, but the connection is very frail in the epispadiac condition. English, in fact, reported one case where the corpora were completely separated. In some cases the separation may be made without cutting. In the technic of the operation I have learned in the case in which I assisted Dr. Martin that it is well to carry the dissection well up under the pubes so as to mobilize the trough freely, and then to make the canal carefully before separating the corpora and carrying it to its place under the organ. One difficulty in the operation is to get the canal placed far enough forward in order to allow for retraction. In some cases a second operation will be required to locate the meatus properly. I believe the addition of the Van Hook plan, as carried out by Dr. Bullitt, will prove of decided benefit, because it assures the meatus at the proper point, and I feel personally indebted to Dr. Bullitt for showing by his case that it has distinct advantages.

Dr. E. D. Martin, New Orleans—My case amounted almost to exstrophy of the bladder. It was necessary to dissect an anterior flap from the pubis in order to complete the upper border of the urethra. This was sutured on either side and the tube, being completed, was buried between the corpora. The case has been greatly improved, though the incontinence has not been entirely overcome. This I hope to correct with the use of paraffin injections.

In regard to hypospadias, I would like to make a suggestion which I think is of some value. I had very recently a case in which I tried the suggestions of both Rochet and Nove-Josserand. The method of the former of making a tube of scrotal tissue and passing it under the skin was only partially successful. The latter, of wrapping a Thiersch graft around a catheter and pulling it through the slit, failed also, and I then divided the corpora the full length of the deformity, laid them wide open and covered the entire raw surface with a Thiersch graft. This succeeded beautifully. I then brought the corpora together, forming a deep groove all the way. I pared the edges freely, held the corpora in position with mattress sutures and sutured the margin of the skin with catgut. All united, with the exception of a small fistula on the junction of the newly-formed canals, and I agree with Dr. Bullitt that these are always difficult to close, and that perineal drainage is always necessary to insure success.

Dr. Erasmus D. Fenner, New Orleans—I had a case in which I had an opportunity to treat acute epispadias, and my case was very considerably below what I believe to be the proper age limit in these cases. The patient was not quite five years of age. Fortunately for me, however, the little boy was remarkably intelligent for his age, and assisted me in every possible way by his great patience, thus overcoming the objection that has been made to doing the operation at this age. In connection with this operation I wish to say that my knowledge of the procedure is due entirely to the excellent recollection of my friend, Dr. Parham. Shortly afterward I had an opportunity of seeing Dr. Martin's case, and the steps of the operation were simply the mere separation of the parts by Cantwell's procedure. I was impressed, first, by the expansibility of the tube, and second, I was impressed by the fact that it was free, so that it could easily be drawn up above the urethra after it had been placed in its position. I was further impressed by the absolute necessity of using a silk suture. Up to that time I had used chromicized catgut. I decided to use internal silk suture. The approximation was satisfactory, and for a few days the case did well, but shortly afterwards the parts began to swell, and there developed between the skin and the urethra a large abscess which subsequently required opening up of the skin, and breaking the abscess and allowing it to escape. Fortunately, however, the operation was not associated with any serious fistula in the new canal, and after a rather tedious convalescence, my little patient recovered, having a perfectly normal restoration of the anatomy, although I found that the meatus was placed a little too far back for the normal condition. I have not yet made up my mind how to unite that. I am convinced, however, if we could let the patients wait until they are 10 or 11 years of age, so that they can have control of the bladder, we could get much better results.

I have suggested this same procedure for hypospadias. Not long ago I had an opportunity of operating on a patient suffering from hypospadias. In this case, we concluded that we would leave out the buttonhole in the peritoneum. The patient left after the operation in a very much worse condition than before. Taking this case into consideration, as well as my case of epispadias, it would seem that the buttonhole in the peritoneum should not be omitted.

Dr. James B. Bullitt, Louisville—The speakers have testified that this operation gives fairly good results, and in some cases surprisingly good results. I would have liked to have heard from some of the other gentlemen who have employed other methods in regard to what they have been able to accomplish. I have only had two cases of this condition, and the first case was operated on by the method usually applicable to hypospadias, and the patient was not improved, and I have no doubt that there are others who have had the same experience. So it is especially gratifying to me to have accomplished the result I did in the second case. Outside of this small fistulous opening the patient was cured, and he got up inside of three weeks' time. I agree with Dr. Fenner that the drain-

age of the bladder through the perineum is always necessary. I believe also when you have a fistula it would be better to drain the bladder through the perineum.

What part of the operation is the most difficult? In the first place getting the mucous membrane clear to the end of the glans penis. It is nearly always impossible to find sufficient mucous membrane to reach to the end of the glans penis. While the urethra can be drawn out surprisingly, it also retracts afterward somewhat surprisingly. I am sure that Dr. Parham is entitled to great credit for the suggestions he has made. I believe in the case I operated on, if I had separated the corpora cavernosa further back, I would have had a better result, and this fistula would probably not have occurred. The third point is that the formation of the canal from the point where the abnormal meatus is situated is somewhat difficult. However, I believe from the success of this operation in my own particular case, and from these other operations that have been reported, that it is very much superior to any of the other operations that have been proposed.

TUBERCULOSIS OF THE MAMMARY GLAND.*

A. H. LEVINGS, M.D.
MILWAUKEE, WIS.

Dr. Scudder,[1] in an exhaustive article on "Tuberculosis of the Mammary Gland," states that an examination of the literature showed only eighty cases reported up to that time, twenty-three of which were rejected on account of imperfect data. This list, however, does not include twelve cases reported by Albert in his work on surgery.

Tubercular infection is so frequently met in the various tissues and glands of the body that it seems unusual that only fifty-seven well authenticated cases of tuberculosis in the mammary gland should have been reported up to 1898. It is, of course, to be expected that not all cases diagnosed as tuberculosis of this gland were reported, but had they been, the number would still be small, and the cases reported since 1892 are so few that we are forced to believe that the disease often goes unrecognized.

It is conceded that tuberculosis of the mammary gland is most frequently found in young women between the ages of 20 and 35, or during the period when the gland is functionally most active. A few cases have been reported as occurring before and after menstrual life. Roswell Park reported a case in a girl 12 years of age, and Mr. Payne saw an infant with a tubercular abscess of the breast, following which there was general tuberculosis and death. Several other cases have been reported at ages under 20. Cases have also occurred in women after 50 years, and even after 60 years of age. The condition is occasionally observed in men. In Dr. Scudder's eighty cases six were males, and in forty cases reported by Mandry one was a male. It is said that more than one-half of the women affected have borne children, and that in a considerable number of these the process has originated during pregnancy.

It is held by the great majority of writers, and this I believe to be true, that the process is to be observed most frequently in spare, weakly, anemic individuals, in those who have inherited the so-called scrofulous diathesis or tubercular predisposition, and especially in such as have a parent or near relatives who have or are suffering from tuberculosis. Tubercular infection of the mammary gland may be primary or secondary. When primary it may occur through the milk ducts or through abrasions of the nipple or of the skin covering the breast. It is thought that the great majority of cases are secondary to a tubercular process in the lymphatic glands of the axilla or neck, or to one in an adjacent rib, pleura or lung. The focus, however, may be situated in distant bones, in the genito-urinary or intestinal tract, in the peritoneum or skin. When secondary and the foci are situated more or less remotely, infection may occur, and frequently does, through the arterial circulation. Infection undoubtedly takes place, however, in many of these cases through the lymphatic circulation by a retrograde process. Retrograde infection or infection carried against the lymph current is seen every day in cases of carcinoma. A case of epithelioma of the nipple came under my observation in which there were metastatic growths in the membranes of the brain, these having taken place through the lymphatic circulation. It is also of frequent occurrence in carcinoma of the mammary gland to observe enlargement of the lymphatic glands of the neck. Although it is held that the bacillus of tuberculosis is non-motile, it is probably true that these bacilli are often carried against the normal lymph current by cellular action or by reverse currents. Infection may also occur by contiguity of structure in cases where the submammary tissues, the adjacent ribs, or parietal pleura are implicated. If infection occurs through the milk ducts, the process must be situated primarily within the ducts or the acini. If the bacilli reach the breast through the circulation, lymphatic or arterial, they would naturally be arrested in the tissues directly surrounding the alveoli, as here the arteries which supply the gland break up into a network of capillaries, while the lymphatic radicles take origin within and about the lobules of the gland. When infection occurs through contiguity of structure the connective tissue of the gland will be primarily implicated.

THE ANATOMY.

It might be well in this connection to review briefly the anatomy of the lymphatics of the chest for the purpose of determining the possible channels of infection to the mammary gland through these vessels. It is generally held that the lymphatics in the mammary gland of the female are more highly developed than they are in any other gland in the body. They are generally divided into two groups, the superficial, which passes to the axilla, and the deep, which follows largely the branches of the internal mammary artery and goes to the anterior mediastinum. The axillary glands may be divided into three chains. The first, or superior, lies along the lower border of the pectoralis minor muscle, and is in relation with the long thoracic vessels.

It receives most of the lymphatics from the upper and outer portion of the mammary gland, the front of the chest and from the abdominal wall above the umbilicus. The second or middle chain is situated in the adipose tissue of the axilla and on the inside of the axillary vein. It receives the lymphatics largely from the upper extremity, and the efferent vessels from both the superior and posterior chains. The posterior group lies along the posterior border of the axilla in relation with the subscapular vessel. It receives the lymphatics from the scapular region of the back and from the inner and lower quadrant of the breast. The deep lymphatics of the gland anastomose freely with the superficial and with those from the pectoral fascia. Some of these vessels from the outer side go to the axilla, while others accompany the intercostal vessels and enter the

1. Amer. Jour. Med. Sci., July, 1898.

right lymphatic or left thoracic duct. The deep lymphatics, which originate in the inner hemisphere of the breast and in the inner portion of the pectoral muscles, penetrate the second, third and fourth intercostal spaces and communicate with the glands, six or eight in number, which are situated along the internal mammary artery.

LYMPHATICS OF THE LUNGS.

There are two sets, the superficial and deep. The superficial is placed beneath the pleura as a minute plexus covering the outer surface of the lung, communicating freely with the pleural cavity, and invading the interlobular tissue. It terminates at the root of the lung in the bronchial glands. The deep set commences in the mucous lining of the bronchial tubes and accompanying the vessels terminates in the pulmonary lymphatic glands situated along the walls of the small bronchi and in the angles of their subdivisions. There are about forty glands in the right lung and thirty in the left. Efferent vessels from these pulmonary glands join with the superficial lymphatic vessels and end in the bronchial glands. The efferent vessels from the bronchial glands communicate with the mediastinal glands and traverse the tracheal and esophageal glands, terminating on the right side in the right lymphatic, and on the left in the thoracic duct. There may be, then, a direct circuit of lymph by retrograde action from the neck and axilla to the breast, and from the lungs, pleura and pulmonary and bronchial glands through the mediastinal glands and their lymphatics along the branches of the internal mammary artery to the breast. The arteries which supply the breast are from the thoracico-acromialis to the upper lobes, from the long thoracic and external mammary to the outer lobes, and from the anterior intercostal and perforating branches of the internal mammary to the inner lobes. Each gland consists of from fifteen to twenty tubo-racemose glands bound together by connective tissue and united into a hemispherical mass by adipose tissue. Each lobe has its own excretory duct. The acini, either sacular or in the form of tubules, are grouped together to constitute lobules. They are limited by a distinct membrane and lined by either columnar or polyhedral epithelial cells. The blood vessels run mostly in the superficial tissues radiating toward the areola, and from these vessels branches penetrate into the glandular mass and pass between the lobules, giving off twigs which break up into capillaries enclosing the alveoli. Naturally, then, if the bacilli are brought by the blood vessels to the gland they would become implanted on the alveoli or they might pass through their walls into the interior. The latter unquestionably may occur, and does during lactation. If the bacilli are arrested in the capillaries the tubercular process set up would be an interacinous one. If they pass into an acinus or duct and become arrested the infectious process would be within the acinus or duct. The lymphatics also run in the connective tissue stroma of the gland and commence as a network of capillaries within and around the lobules. Their radicles have practically the same distribution as have the capillary blood vessels. In consequence of a retrograde action in the lymph current the bacilli would also become implanted about the acinous wall, or possibly carried into its interior.

PATHOLOGY.

The bacilli being implanted within the tissues of the gland set up an irritation which is followed by the usual pathologic change. Round cell infiltration occurs with the formation of epithelioid and giant cells. The bacilli are often to be found in the exudate, while tubercles or tubercular masses with caseation or pus formation often occur. It is characteristic of those cases which remain for a long time as hard nodes for the microscope to show the formation of a large quantity of interacinous connective tissue. In a considerable number of my cases some of the hard nodes were made up largely of dense fibrous tissue situated between sparsely distributed acini. In these cases there will be areas of distinct caseation or those in which giant cells are to be found or the bacilli of tuberculosis and even in some in which these conditions are not demonstrated the axillary glands will show caseation and the bacilli of tuberculosis. In cases in which the infection is directly through the milk ducts or glandular structure, the process, aside from its situation, will be much the same as before with the exception that in a considerable number of these pus may be forced from the abscess cavity by pressure along the ducts and from the nipple.

SYMPTOMS AND COURSE.

The clinical picture presented by a tubercular process within the breast is a variable one. It will depend largely on the stage of the disease during which the examination is made, on the number of foci primarily infected, and also on the fact as to whether the process is primary or secondary. In many of these cases, as can be readily appreciated, the primary disease will be of such importance or severity that the condition of the breast, even if severe, will be of little or no moment. The patient's attention may first be called to the process by pain which is usually early experienced, pretty continuous and has a dull, heavy, aching or burning character. Not unfrequently, however, the pain is scarcely noticeable, and the patient's attention is first attracted to the breast in consequence of finding therein a node or nodes. These nodes, and there are usually more than one, are reasonably hard, not very sensitive and quite irregular. They can not be distinctly separated from the glandular structure, and ordinarily vary in size from that of a hazel nut to half an inch or an inch and a half in diameter. They are very seldom round, but are flat or have a very irregular contour. These nodes are often distinctly separated, but still lie in the same quadrant of the breast. The fact of their being multiple nodes is a characteristic of the disease. The gland as a rule is not enlarged, and on simple inspection nothing may be seen. The axillary glands during this early stage are enlarged and may be palpated. As the condition progresses the nodes increase in size, though very slowly, possibly coalesce, become more elastic, and finally impart a sense of fluctuation. They may become adherent to the skin and the contents of the abscess be discharged through a fistulous tract. Occasionally several fistulæ are formed in consequence of the breaking down of many nodes. While ordinarily the gland is not enlarged during the first stage of the disease, later, if pus in any considerable amount is formed, the breast becomes noticeably enlarged. If the process is situated near the posterior surface this may become attached to and quite immovable from the pectoral fascia. The nipple, in a goodly number of cases, is retracted.

DIAGNOSIS.

The diagnosis will depend on the antecedents and appearance of the patient, the history of the case and the physical examination. The antecedents will often show scrofula or tuberculosis. The appearance is often that of a thin, anemic, weakly woman of lessened resist-

ance, while the history may establish the probability of tubercular processes in other parts of the body. The examination will usually disclose, if made before the formation of an abscess, one, more frequently two or three, quite hard, very irregular, well defined, not specially sensitive nodes which are inseparable from the glandular structure. The axillary glands are enlarged—it is stated in two-thirds of the cases—and the nipple often retracted. When pus has formed the use of the hypodermic needle and the microscope will materially aid in establishing the diagnosis. When fistulæ have formed, the process being chronic, the diagnosis is easy. The process must be differentiated from scirrhus, actinomycosis, benign growths and from cysts due to chronic inflammatory processes. In scirrhus the patient is usually more than fifty years of age. The node is single and harder than in tuberculosis. The history of the cases and the cachexia are different. In actinomycosis the thickened, indurated, leathery skin, the yellow granules and the use of the microscope will establish the diagnosis. In benign growths, such as fibroids, the fact that they are usually single and distinctly encapsulated without enlargement of the axillary glands, will be sufficient to distinguish them. Multiple cysts, especially when of small size and due to a chronic inflammatory process, present the greatest difficulties perhaps in the way of diagnosis. Many of these small cysts are not to be differentiated by touch from solid nodes. In these cysts, however, the axillary glands are not usually enlarged, the history of the case is often different, and the use of the hypodermic needle will afford valuable assistance.

I have been able to find scarcely more than a dozen cases reported up to date in the United States, and believing that very many of the cases of chronic mastitis and most of those of chronic abscess of the breast are really tubercular, to say nothing of those cases in which there are distinct nodes running a chronic course, I am forced to the conclusion that in the past there has been in the great majority of cases of tuberculosis of the mammary gland a failure to make a diagnosis.

REPORT OF CASES.

Seven cases of tuberculosis of the mammary gland, all in females, have come under my observation during the past two years. Five of these patients were single. Of the two who were married but one had borne children. In three cases both breasts were affected.

CASE 1.—The first patient was 35 years of age and single. She had noticed for a year and a half an enlargement first in the right and then in the left breast. In placing the palm of the hand flat against the gland many small indurations could be felt. These seemed of considerable size when the breast was pinched up between the thumb and fingers. The nodes were hard, irregular and reasonably well defined, but seemed to be a part of the glandular structure. The axillary glands on both sides were implicated. The nipples were not retracted. The patient's condition, aside from this, was reasonably good.

Both breasts and axillary glands were removed. The breasts were found dotted with small circumscribed abscesses, which in some cases were directly connected with the ducts and in which the bacilli of tuberculosis were demonstrated to exist. Patient made a good recovery. In this case there was nothing in the patient's history or antecedents indicative of tuberculosis and there were no other foci anywhere in the body which could be detected.

CASE 2.—An unmarried woman, 30 years of age, with a predisposition to tuberculosis, noticed seven months previous to examination, a gradually increasing, hard swelling in the right axilla. Latterly the swelling had occasioned such extreme pain in the right arm that it was scarcely endurable. During the past two months several small, hard, well circumscribed indurations could be felt within the breast structure.

The breast was excised, and with it the major portion of the pectoral muscles. An abscess of considerable size situated in the axilla and adherent to the pectoral muscle was unavoidably broken into. A large number of axillary glands were so intimately adherent to the axillary vein that excision of a portion of the vein was necessary. This was done after double ligation with catgut. The glands and abscess were causing severe pressure on the brachial plexus, some of the smaller branches of which were excised with the abscess. The breast was found on multiple incision to contain a large number of small collections of pus, many of which were not larger than a pea. Some of these were in direct connection with the ducts. The patient had never complained of anything more than an occasional burning pain within the breast.

Patient's family history was as follows: Her father was drowned, mother died of pneumonia at an advanced age, an uncle and a cousin died of consumption. There were three children, all of whom are living. The glands of the axilla showed numerous tubercular bacilli as well as many points of caseation. The process in the breast in this case was evidently secondary to the infection of the axilla.

CASE 3.—Mrs. R., aged 40, mother of three children. Very spare in figure, anemic, presents the appearance of one having but slight physical resistance. In her family history a relative of her father was supposed to have died of tubercular peritonitis, while a brother had his leg amputated for tuberculosis of the bone. After the birth of her third child eight years previously she suffered from a mammary abscess, and has been since in poor physical condition. For the past few months the patient had noticed a small, hard lump in the left breast. At the time of the examination there were two very noticeable, quite hard, reasonably well-defined nodes which evidently were inseparable from the glandular structure. One was in the upper and the other in the lower quadrant of the left breast. In the right breast there were also two or three indurations. From one of these, when pressure was made, there was a discharge from the nipple. The nipples were not retracted. The glands in both axilla were enlarged.

The breasts and axillary glands were removed. The pathologic findings showed that the glands were tubercular. The patient, one year after the operation, shows indications of pulmonary disease.

CASE 4.—An unmarried woman, aged 31, had been for several years in delicate health in consequence of a chronic uterine and ovarian inflammation. She had worked hard as a nurse and was thin in flesh, debilitated and anemic. Her family history shows the father and mother to be living and well. There is no tuberculosis in the immediate family. A brother of the father and a sister of the mother, however, died of consumption. For four years patient has noticed a gradually-increasing enlargement in the right axilla. For a few months there has been some soreness and hardness in the right breast with slight fever. The axillary glands have caused the patient a good deal of pain. In the breast there is an illy-defined, not well circumscribed induration situated in the upper quadrant. If the breast is picked up between the thumb and fingers there is a marked induration.

The breast and axillary glands were removed. The breast, on incision, showed that the hardened area had undergone caseous degeneration. The axillary glands were found to extend along the vessels filling more or less the axillary space as far as the clavicle, making a section of the pectoral muscles necessary in order to remove them. Many of the axillary glands were in a state of caseous degeneration, and contained bacilli in large numbers. The patient, since the operation, has shown decided improvement, and although at times annoyed by a cough she has gained in flesh and strength.

CASE 5.—A single woman, aged 44. Father and mother lived to be old. No tuberculosis in family. Patient had a severe pulmonary hemorrhage twenty years ago and a second one year ago. Both from the right lung. In the right apex there is prolonged expiration with much rattling and a decided dull-

ness. There is considerable cough and some expectoration. The latter contains tubercle bacilli. During the last eight months there has appeared in the left breast, just above the nipple, a mass two inches long by half an inch in thickness. This area is quite hard, and from it several strands pass out to the border of the breast, while two or three run in toward the nipple. The axillary glands are enlarged. Patient, although having some continued fever, looks comparatively well.

Operation was not advised on account of the condition of the lung.

Case 6.—Female, aged 30, of spare figure, is anemic and not strong. Never, however, has suffered any serious illness. Family history good. For several months she has noticed hardened areas in both breasts. The condition has caused a good deal of anxiety and the patient has apparently lost flesh and strength. Has no cough. On examination there are several indistinct and separate hardened areas in each breast. Nipples not retracted. Glands in both axillæ enlarged.

Axillary glands and breasts removed. Sections show hardened areas in the breast and the axillary glands to contain caseous material in which the bacilli of tuberculosis are found.

Case 7.—Female, aged 36. Married nine years; never pregnant. Spare in figure, weak and anemic. Never has been ill. Family history good. She has noticed in the right breast more or less of pain for the past three months, also a swelling, which has gradually increased in size. At the time of examination there was a reasonably soft, fluctuating growth the size of a hen's egg situated in the upper and outer quadrant of the gland.

The mass was only mildly sensitive on examination. There were also several small indurations in the breast. The axillary glands were distinctly enlarged. Patient's temperature was not above 99. In the outer quadrant of the left breast there was also a soft, not well-defined and fluctuating mass as large as a small orange, while directly above the nipple were two hard and not well-defined indurations. Glands in both axillæ were enlarged.

The patient refused to have the breast entirely removed, consequently free excisions were made of the fluctuating masses, these excisions being made to include the indurated areas. In cutting across the ducts many of these were seen to be in intimate relation with the abscess cavities and to contain pus. The pus in both cavities was found on microscopic examination to contain the bacilli of tuberculosis.

Of these seven cases two were secondary to tuberculosis of the axillary glands, while one was secondary to tuberculosis of the lung. Of the six cases operated on five seem to have completely recovered.

TREATMENT.

This will depend largely on the general condition of the patient and the extent of the disease in the breast. If the process in the gland is secondary to a severe and non-curable condition situated elsewhere in the body nothing more than palliation should be practiced. If the infection in the gland is secondary and the primary focus not severe or amenable to treatment, then there should be an effort made to eradicate the infection in the gland. If there be but a single collection of pus without adjacent nodes, indicating but a single focus of infection, the abscess may be incised, washed out thoroughly, curetted and drained. This course has been successfully practiced, and is recommended by Warren. If multiple foci of infection exist, and they are confined to a single quadrant of the breast, this portion may be excised. It is, however, the better practice where dissemination has occurred to excise the entire breast. If the axillary glands are implicated, as they usually are, they should be removed.

CONCLUSIONS.

Tuberculosis of the mammary gland is not an unfrequent condition, but one which goes unrecognized. The process may remain for months, and even years, in the form of hard, irregular, reasonably well circumscribed nodes. Liquefaction and pus formation are secondary and later processes. Tuberculosis of the breast occurs with especial frequency during menstrual life. It occurs with greatest frequency in single women. The condition is more often primary than has been generally supposed. The tubercular infection often implicates both glands nearly simultaneously. Palliative treatment may be practiced when the process is circumscribed. When the processes are diffuse radical measures should be recommended.

DISCUSSION.

Dr. B. B. Davis, Omaha—A case under my observation had a very large tumor and the axillary glands were considerably involved. At one point in the breast there had been a perforation and fistula with a history of considerable material being discharged, which under microscopic examination was demonstrated to contain tubercle bacilli. In the other case, I think I should have erred had I not recently read a very able article by a German operator, in which he discussed in detail the operation. This was in a comparatively young woman, about 30 years of age, if I remember rightly. Although there seemed to be one nodule, it was separate and I found on examination that it consisted of three different nodules, agglutinated and in a state of degeneration. All I did was to excise that portion of the process containing the nodules. There was no enlargement of the axillary glands and the patient recovered. In the other case I did the same kind of an operation that I should have done if the case had been carcinoma of the breast.

Another point is in regard to the temperature. In these tubercular cases which have existed for any considerable length of time we nearly always have some rise of temperature in the evening, and frequently subnormal in the morning, and this was particularly characteristic in the first case I mentioned. I have been under the impression that a good many of these cases in which there is a hard nodule of the breast and the breast is removed, supposedly as a carcinomatous case, are in reality tubercular, and I believe tuberculosis of the mammary glands is a much more common condition than is generally supposed.

Dr. T. J. Sullivan, Chicago—There is no reason why tuberculosis should not be found in the mammary gland, just as it is found in every other portion of the body, and I believe that there is no tissue of the human body that is not liable to be infected. I think we can even go further and recall the statement of some of the authors that the tubercular germs in a greater or lesser number exist in all our bodies and that sooner or later we may, any of us, have it. That being true, we may find the tubercular germs in any portion of the body.

I had a case of this condition occurring in a woman, of average health, mother of ten children, who had always enjoyed good health, and had been compelled to work hard to maintain the family. She had had swelling in the breast, appearing about six months previously, after working hard. Previous to presenting herself to me for examination she had been examined by a physician, who informed her that she had carcinoma. The appearance would indicate that she was suffering from carcinoma. I placed my hand on the breast immediately over the tumor and detected a small, hard nodule. In presenting her to a class of medical men the following diagnosis was made: Retraction of the nipple; hard nodule; no axillary enlargement; healthy and well; no pain.

She was kept under observation for a couple of weeks, at the end of which time the nodule had enlarged slightly. I then was in considerable doubt as to the nature of the tumor and removed a small wedge under local anesthesia. Pathologic examination of this wedge revealed the fact that it was due to an inflammatory process. I then decided to remove the whole breast in a radical operation, including the axillary glands. I did so, and the appearance of the nodule presented to my mind the appearance of scirrhus of the breast,

and a good pathologist who was present at the observation said that undoubtedly it presented all the appearances of scirrhus. The operation was complete, however, without further attack on the axillary glands, and subsequent pathologic examination revealed marked tuberculosis, which healed rapidly.

It is time to call attention to this subject and give these patients the advantage of early operation.

DR. WILLIAM KNIGHT, Hartford, Conn.—Just a little criticism of one point in regard to abscess. Dr. Levings said you could open the tumor and drain thoroughly. The tendency in treatment of those cases is to prevent absorption. It seems to me that it is folly to interfere with it. It also seems to me much better to open it and drain thoroughly with plenty of absorbent cotton. I think we will get much better results by the treatment of abscess in this manner.

DR. ANDREW W. MORTON, San Francisco—I have had experience with only one case which puzzled us considerably. We used the tubercular serum to make the diagnosis, and got the characteristic reaction which we usually get in using this serum where there are tubercles. After the removal of the gland the microscopic examination showed the diagnosis to be correct.

DR. A. H. LEVINGS, Milwaukee—I may add that one additional case has come under my observation since this article was written. Of my cases of tuberculosis of the mammary gland one was secondary to a tubercular process of the lungs, while two were secondary to tubercular processes in the axilla. The others, so far as I was able to determine, were primary within the breast itself. In some of these I think the infection was through the milk ducts. In others the infection was through the circulation, arterial or lymphatic. I am very confident that we have been mistaking these cases for carcinoma because the two conditions may present practically the same symptoms, in that there is a hard nodule, retraction of the nipple and enlargement of the axillary glands.

In regard to the treatment of opening and curetting an abscess, I am of the opinion that in a case in which there is but a single abscess with no out-lying nodes, this treatment may be recommended, and probably will, if properly carried out, result in a large number of cures. This, in fact, is the treatment generally which we are accustomed to follow in cases of tubercular abscess.

ABSCESS OF THE SPLEEN.*

WALTER M. SPEAR, M.D.
ROCKLAND, ME.

Abscess of the spleen is rare, and when a case falls into our hands and is operated on successfully, it is worthy of record.

About the middle of May, 1901, I was called to see Mr. A., and obtained the following history:

History.—American, age 74 years, weight 211 lbs. Family history: Mother and one sister died of consumption. Father died of some brain trouble. Previous history: Has had two severe falls, the last one two years ago, from which he never fully recovered. Jan. 10, 1901, was seized with a severe attack of influenza, which completely prostrated him. At the end of three weeks the temperature and pulse were normal. He has never lived in a malarial district and has never suffered from typhoid or malarial fever. Since the beginning of his sickness he has constantly lost in weight.

Present Illness.—Patient in bed, anemic, covered with a cold perspiration, very nervous, anorexia, night sweats, slight constipation. Complains of numbness in legs and feet, slight though constant pain in left thorax just above lower border of ribs. At times he is pressed for breath, which appears to be due to his nervous condition.

Physical Examination.—Temperature normal, pulse 100, weight about 175 lbs., heart's action very feeble, slight tenderness on deep pressure under lower border of ribs on left side, reflexes normal. I thought that his condition was due to the severe attack of influenza which he experienced. Gave him strychnin and tonics. The improvement in his condition was marked, so much so that in a few days he was up and downstairs. I did not see him again until May 30, 1901. His physician then stated to me that the patient, while being carried upstairs on his son's back the night before, cried out that something had given way in his left side and that he was very faint. He was immediately put to bed and stimulants administered, to which he at once responded. I saw him the next morning and found his pulse 64, and temperature normal. He was very nervous, had a sallow cachectic look, and had lost a great deal of flesh. He complained of constipation, and of severe pain in left hypochondrium. Some edema of legs and ankles was present. His heart was much stronger. Hard tumor in left side extending above lower border of ribs, tender, no fluctuation, urine negative. I considered the tumor malignant, which diagnosis was coincided in by several physicians. Advised exploratory laparotomy.

Operation.—June 8, 1901. On examination under ether I found a hard, non-fluctuating tumor extending from above the lower border of the ribs downward to the crest of the ilium and inward to the linea alba, smooth, most prominent just below ribs. Incision made over most prominent part of the tumor. Found an enlarged spleen very dark in color, which was bound down by numerous adhesions. The anterior surface was comparatively free. Anterior wall of abscess thick, posterior wall very thin, indicating that it would have soon ruptured, allowing contents to escape into abdominal cavity. Because of the thinness of the wall and the numerous adhesions I considered an attempt at removal dangerous. Walled off with gauze and made an incision into the spleen through which was evacuated two quarts of creamy pus mixed with a little blood and cheesy-looking material. Cavity curetted, washed out and spleen sutured to abdominal wall with chromicized catgut, iodoform gauze drain. Convalescence rapid and uneventful and in five weeks he was up and dressed. On Aug. 2, 1901, he suddenly became unable to swallow. Aphasia and hemiplegia of the right side appeared, and after this he rapidly failed and died Aug. 4. 1901. Unfortunately an autopsy was not obtained.

Report of Dr. C. D. Smith, who made an examination of the pus: "I fail to find tubercle bacilli, yet the presence of calcareous material is strong evidence of that nature of the abscess. It contains a multitude of lymphoid cells, much pus, a few crystals of hematoidin showing that there has been a hemorrhagic area in the organ or an embolus, and a few bits of characteristic yellow elastic tissue and fragments of spleen tissue."

Several cases of abscess of the spleen have been reported in which the pus was sterile, and from the absence of any previous septic condition, and the constant normal temperature, I am inclined to think that it was sterile in this case.

I ought to have made a correct diagnosis, but was led astray by the absence of fever, the slight pain, the rapid emaciation and extreme constipation. A blood count would have been of great assistance. Bessel-Hagen thinks the considerable increase of leucocytes in the blood of the greatest diagnostic significance.

The condition in this case was probably due to an embolus lodging in the splenic vessels which, on account of the slowness of the blood-current in terminal arteries, are peculiarly susceptible to the lodgment of emboli.

SUMMARY OF THE LITERATURE.

In looking over the literature on this subject, I have collected 65 cases, 23 of which occurred after an attack of malaria or typhoid fever, 1 after yellow fever and 3 after appendectomy. The others were ascribed to various causes, such as trauma, disease of heart, sudden chilling of the body after excessive heat, tuberculosis, anthrax, alcoholism and exhaustion. Eight cases in which the

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

etiology was doubtful were probably due to malaria, and in eleven the etiology was unknown. Metastatic abscesses have been reported following osteomyelitis, gunshot wound of the knee and amputations.

Grand-Mourcel reports 57 cases, 20 of which were due to malaria; 9 of them diagnosticated, with 8 recoveries, while 11 were recognized only at autopsy. From this it would seem that more cases occur than we are led to believe, which are not diagnosed either before or after death.

ETIOLOGY AND DIAGNOSIS.

The hyperemia of the spleen during malaria and typhoid renders it particularly susceptible to inflammation and abscess formation. All writers agree that the diagnosis is extremely difficult. The chief diagnostic symptoms are history of infectious disease, pain in left hypochondrium which may radiate to left shoulder, night sweats, anemia, loss of appetite and usually chills. Fever may or may not be present; if present, it is of little significance, as it may be due to the original disease. Occasionally extreme constipation is present, but more often diarrhea. Blood count shows increase of leucocytes (Bessel-Hagen). Tenderness on deep pressure usually present in the beginning of the attack. Fluctuation is of value as a diagnostic sign only in those cases which are palpable under the abdominal wall.

In such diseases as malaria and typhoid, in which there is commonly an increase in the size of the spleen, the increase alone is not symptomatic of abscess formation, but if the increase in dulness is progressive, and, added to this there are one or two or all of the above-named symptoms, it is at least very suggestive of abscess of the spleen.

If an embolus lodges in the spleen, it may be some time before any enlargement is apparent, and, in fact, I think that a small abscess may form in this way, become encapsulated, remain latent for a long time, and then either be absorbed or receive a severe blow or strain, which may cause a rupture of the capsule, after which a rapid increase in size of the spleen becomes apparent, or several abscesses may coalesce, forming one large abscess. I believe that this occurred in the case described above, and that the abscess ruptured into the substance of the spleen at the time he cried out, while his son was carrying him upstairs. From this time on the increase in size was remarkably rapid.

PROGNOSIS.

If recognized and operated on sufficiently early, the prognosis is fairly favorable. If not operated on, the abscess may rupture into a hollow viscus and the pus be evacuated by means of that organ. More often it will rupture into the peritoneal cavity and death ensue. Three cases among the sixty-five reported above recovered after rupture of the abscess, one opened into the cecum, one into the left lung, and one into the left lung and stomach.

Death of the patient can be attributed more often to the debility following such diseases as malaria, typhoid and tuberculosis than to the operation or the abscess itself.

TREATMENT.

This is purely a surgical disease. In a few cases splenectomy has been performed, but in order to do this operation successfully the diagnosis must be made very early in the course of the disease, before adhesions have formed. Bessel-Hagen states that splenectomy for splenic, perisplenic and parasplenic abscess was performed seven times, three up to 1890, four in 1891. The same author reports two cases of splenotomy in which the abscess was reached by resection of a portion of the ninth and tenth ribs. Lauenstein also reports one similar case. In the greater number of cases aspiration was first employed, then later incision through the abdominal wall. Splenectomy is the operation to be preferred, but it is limited to those cases in which adhesions have not formed, and to those in which there is no danger of infecting the peritoneal cavity. By this operation we remove the entire organ and its contents at once, thus giving a clean wound, and a much more rapid and satisfactory convalescence. Until we are able to make an early diagnosis, splenotomy is the operation of necessity, and it should be chosen in those cases in which there is great debility and in those in which the abscess wall is thin.

I do not believe that aspiration is necessary in the majority of cases, and its use should be condemned. We should be able to make the diagnosis without its aid, and it subjects the patient to one more chance of infection.

In the early stages of the disease, when the abscess cavity is small and the spleen has enlarged but little, if at all, it is very doubtful if the aspirating needle would throw any light on the diagnosis. Later, when the spleen has increased in size, and possibly fluctuation is present, its use is unnecessary and dangerous. If, after the exposure of the tumor, it is found to be very large, it is wise to aspirate before making a free incision into the spleen, thus diminishing the danger of infection.

CONCLUSIONS.

1. Abscess of the spleen is rare, but not as rare as we are led to believe.
2. It is most likely to occur after malarial or typhoid fever, because of the hyperemic condition of the spleen in these diseases.
3. Absence of fever does not preclude the possibility of an abscess.
4. Early diagnosis and operation are very essential, and give a fairly favorable prognosis.
5. Splenectomy is the operation of choice, but its application is limited.
6. Preliminary aspiration is an unnecessary procedure, and its use should be condemned.

ACUTE EPIPHYSITIS CAUSING A CONDITION SUBSEQUENTLY SIMULATING CONGENITAL HIP MISPLACEMENT.*

JOHN PRENTISS LORD, M.D.

Professor of Surgery Creighton Medical College; Attending Surgeon St. Joseph's Hospital.

OMAHA.

The writer uses the word misplacement, instead of dislocation, agreeing with Tubby, who says that dislocation can not properly be applied to a condition where the bone never was in place; the word misplacement seems to be better suited to describe the congenital condition. Epiphysitis does, however, result in a dislocation, and the condition might therefore be properly called pathologic dislocation of the hip, resulting from epiphysitis.

May 12, 1902, a female child of 2 years was referred to me by Dr. McClanahan. It was delicate, but well nourished. Appearances indicated congenital misplacement of the right hip. Indeed, all the conditions were typical of this condition.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

The history, however, disclosed information which placed such a diagnosis in doubt. At 16 months, when the child had essayed to walk, she was normal, as far as the parents knew. At this time she suffered a severe attack of lobar pneumonia, from which she was convalescing when she had an abscess over the hip, which was incised. Resolution was speedy, and no trace was left on examination save a small scar one line in width and two lines in length, situated 3 cm. below and 1 cm. internal to the anterior superior spine. This history following pneumonia indicated that the abscess was pneumococcic. The history elicited from the attending physicians gave evidence of so speedy a resolution that articular or epiphyseal disease could scarcely be credited, though it was suspected. A periarticular suppuration predisposed by a misplaced hip, excited by the pneumococcus, was thought to be a possibility. The history gave no certainty as to the diagnosis of either congenital hip misplacement nor acute epiphysitis. There was now no evidence of hip disease. The limb was freely movable in all directions save abduction, which was somewhat restricted.

As before stated, the deformity was typical of congenital hip misplacement. A radiograph did not give information which would enable the inexperienced observer to make a differential diagnosis, but the writer ventures this observation, based on comparisons with a number

of radiographs of congenitally misplaced hips, all of which show a lesser space between the upper extremity of the femur and the pelvis. In fact, it may be said that the head of the bone invariably lies in contact with the ilium. The radiograph of the pathologic dislocation shows unusual distance between the pelvis and the thigh bone. This condition indicates not only absence of the head and neck of the bone, but an amount of soft tissue between the bones, which may explain why our best efforts at reduction are thwarted, except in rare cases.

In an attempt at reduction in this case by the Lorenz bloodless method, nothing could be accomplished. The absence of the head seemed to be strikingly apparent. The bone could not be impigned against the pelvis, as it can in cases for which reduction is ordinarily attempted. I was not satisfied with this attempt, however, neither were the parents, who were solicitous that everything be done to remedy the deformity and the disability. Therefore, the Lorenz-Hoffa cutting operation was done. The incision passed directly through the scar of the old incision, which enabled us to demonstrate the true character of the original trouble, i. e., a healed funnel-shaped depression over the capsular ligament indicated the site of the former sinus through which the destroyed epiphysis had been discharged in the form of pus and débris. A dissection into the former capsule showed this to be a closed cavity, practically a dense ligamentous structure, which precluded an approximation of the trochanters and acetabulum. I use the word trochanters advisedly, because none of the head, and practically none of the neck of the femur was demonstrable. The operation, therefore, was a failure. Literature furnishes abundant information on the occurrence of this condition, but little or nothing on the treatment of the deformity and disability. With the evident advancement in the treatment of hip misplacement, the writer has sought information from some of those who would be likely to avail themselves of anything offering encouragement in the handling of these perplexing cases. Wisner R. Townsend writes:

I have seen a great many cases and believe they should be treated as excised hips. Where there is no adduction and the upper end of the femur does not slip too much, a high shoe will suffice. If adduction exists I overcome it under ether, and put the limb up in marked abduction.

I have not treated any by the so-called Lorenz method, but could only believe it might be of use providing the upper end of the femur could be kept in the acetabular cavity, or in front and below the anterior superior spine, and a new socket thus formed with upper end of femur taking the place of the head, which has disappeared.

That these cases, when seen long after recovery, are very rarely correctly diagnosed is a fact, and I have had a number sent to me on the supposition that they were congenital dislocations.

Royal Whitman says:

I have performed both the open and the Lorenz method in these cases. The aim is, of course, to fix the femur in, or about, the acetabulum, that is, anterior to it, and to hold the limb finally for a long time in abduction and extension. One hopes thus to attain security.

One can hardly report on final results until many years have elapsed. My cases are still under treatment. Perfect cures are, of course, out of the question.

A letter from Professor Lorenz (whose work I had witnessed two years previously) replying to my letter requesting information along these lines, is of especial interest in this connection, and is as follows:

The diagnosis can always be made; the treatment can be the same as in cases of congenital hip dislocation, but never a perfect cure can be obtained. An improvement, however, is nearly always possible. Generally the head of the femur is more or less destroyed, sometimes nearly wanting, so that the upper extremity of the femur ends like a broomstick.

The first who called attention to these cases was my late master, Professor Albert. Reduction, as a rule, is scarcely possible; only one time I succeeded. In the other cases (they are rather frequent, these cases of pathological luxation after osteomyelitis or other infectious diseases), I change only the position of the leg, the flexion and adduction of the thigh being changed in an habitual abduction (lyorrhesis abductionem) and hyperextension of the thigh. I call this treatment, which is available also in other cases *die Functions verbesserung defecter Huftgelenke*. The condition for weight bearing is improved, the endurance in walking is augmented, but the limping will never disappear, although it can be lessened, too.

With this additional testimony, the writer would now be disposed to undertake this treatment, indorsed by practically all three of the distinguished authorities quoted, yet he would have reasons to doubt its usefulness in a case such as the one herewith reported. The treatment would seem rather severe to inflict, where so small a prospect of benefit is promised. The limp and disability, always unilateral in the cases, are really not so great as to be a serious handicap. Some years of experience will probably be necessary before the profession can decide fully the merits of intervention.

While the writer, with his limited experience, which was characterized by failure, would not desire to pose as a pessimist, yet it appears to him that the very nature of the anatomico-pathologic conditions present would seem to effectually preclude the possibility of successful treatment in many of these cases. That cases without too much destruction of the femoral head and neck will be improved by the approximation of the bone to the acetabulum, or placing it anterior and maintaining the parts in this position for a long time, as in congenital misplacement, seems not unreasonable, and, in view of the fact that nothing better is offered, should be tried.

That cases of epiphysitis occurring in young infants where the head and neck of the bone are largely cartilaginous and in a condition favorable to be destroyed completely, will leave a condition unfavorable to successful treatment, except as recommended by Townsend, i. e., as excised hips, by an extension sole to lessen the limp, and the inevitable scoliosis resulting from a tilted pelvis, would appear to be about all that can be done in some of these unfortunate cases.

Discussion such as is hoped to be elicited will favor a better understanding, perhaps, and tend to crystallize ideas relating to what now seems to be little understood generally and rarely practiced, save in the practice of a very few orthopedists.

DISCUSSION.

Dr. John Ridlon, Chicago—Some weeks ago Dr. Lord asked me for facts concerning this condition, and I told him that I had no recollection of any case, and, so far as I could ascertain, I had no record of any case that appeared to resemble congenital dislocation of the hip. By one of those curious circumstances two such cases have since come to me; one of them I have operated on and the other is waiting to see the results of the first operation. Both of the cases were in children and were of sudden onset, accompanied with great pain. Neither had had any abscess that was ever recognized or opened, and there were no scars. I was inclined to believe that it was a pneumococcus infection, and I was somewhat surprised at Dr. Lord's statement that his case was one of pneumococcus infection, and that there was an abscess, because I was under the impression that one did not get abscess in the pneumococcus infection. Now in these two cases the edge of the acetabulum was ragged and the greater trochanter was one-half inch or more above the upper border of the acetabulum, and the line of junction to the shaft where the neck had been was ragged. In the first case, a colored child, I found what I thought possibly was the shell of the former head of the bone, it being somewhat of that size and shape. Under an anesthetic I ventured to pull the leg down, so that the greater trochanter would be in the neighborhood of the acetabulum, and force it into the acetabulum, thinking that I might renew the inflammatory condition, and more likely cause the formation of adhesions which might result in permanent fixation. As I did the operation I could hear a crash, as though some partly diseased portion of the bone was being crushed. I could not make out whether it was the acetabulum or the greater trochanter. The patient has not recovered fully from the operation, but there is no pain, sensitiveness or temperature, and the patient appears to be perfectly comfortable.

The other case resembled the first exactly, excepting that the shell of the head was wanting, and there was a transparent area below the greater trochanter, as if the bone had been partly destroyed. I suggested in the second case the same operation as in the first. It seems to me that the only chance of securing satisfactory results is in pulling the greater trochanter down and placing it in contact with the acetabulum, holding it in place by mechanical appliances for many months and then, if necessary, putting on a leather support to hold it in place for many years. I do not think one should fear the inciting of undue inflammation, as it would seem by this inflammation we would get a greater degree of fixation and better results.

Dr. Wisner R. Townsend, New York—This paper, it seems to me, is particularly opportune, for the reason that the country is being scoured for patients with supposed dislocation that some surgeon may reduce a la Lorenz. The first question to be considered is that of diagnosis. If the diagnosis is correctly made the subsequent treatment may be correct. If it is incorrect it is very uncertain what the treatment may do. One point that seems to me of especial importance after the diagnosis, is the future of the child. I have had the misfortune to be able to follow some of these cases for ten or fifteen years, and those which were neglected were far worse off than those which were cared for. To my mind the points of most importance are to keep the thigh abducted and prevent irritation. The cases should be kept under observation for many years. The thigh can be placed in a plaster-of-paris bandage or a leather support or splints, if desired, and much good result. As far as reducing the supposed dislocation by the Lorenz method is concerned, I do not believe that we can accomplish much except by putting the bone in an anterior position. I have never seen a case of congenital dislocation in which you could not feel the head of the bone; sometimes it is very distinct, although deformed. In acute epiphysitis the head is almost entirely absent, and if the history of the previous abscess is secured it is a rather easy diagnosis to make. Without the head of the bone, of course, we can never have as perfect motion as in the normal child, and no method of treatment can restore the head.

Dr. John P. Lord, Omaha—Just a word in regard to the pneumococcus. As I have said, this condition was only suspected because the child had pneumonia. It occurred after the child was convalescing and, of course, a mixed infection might have caused the suppuration and the discharge. The remark made by Dr. Ridlon that pneumococcus infections of the joints do not terminate in abscess would tend to confuse us, if we continued to depend on the presence of the scar for diagnosis. The writer felt somewhat backward about bringing before the Section a subject which was so rare and of so comparatively

little general interest, because I find that very few are informed outside of those working in special lines, and even these are undetermined. It is, therefore, very important, as Dr. Townsend suggests, that this matter be discussed at this time, in order that we may get our minds clear on this subject.

THE TREATMENT OF UNCINARIASIS.*

THOMAS A. CLAYTOR, M.D.

Professor of Materia Medica and Therapeutics, Columbian University; Physician to Garfield and University Hospitals.

WASHINGTON, D. C.

The treatment of uncinariasis may be considered under three headings: First, the prophylactic treatment, or that directed toward the prevention of infection by the hook-worm; second, the means used to cause the expulsion of the parasite; third, the treatment of the anemia and debility resulting from the infection.

Prophylaxis is of very great importance, and is a subject which requires careful consideration. It seems probable that infection takes place chiefly through the mouth, either in infected water or food, or through contaminated hands, which carry the parasite to the mouth. Looss, however, has apparently proven that the larvæ may penetrate the skin. A possible entrance through the air passages has also been suggested, but does not seem probable.

A most important fact, and one which greatly simplifies the treatment of uncinariasis, is that there is no increase in the number of parasites in the intestinal tract of the victim. Each hook-worm is taken into the system in the larval state, and then develops into a mature parasite capable of producing eggs which must, however, be passed from the host before they can be hatched. Thus it seems probable that the removal of a sufferer from an infected locality to one free from infection would ultimately result in recovery, if the vitality had not been already too much taxed.

MODE OF INFECTION.

The eggs are deposited in the fecal evacuations, and are, under favorable circumstances, hatched in twenty-four to forty-eight hours. In the larval state they become scattered in water or soil, and are now ready to infect the host who swallows them, or whose skin they penetrate.

Since the primary infecting agents are to be found in the evacuations, the important question seems to be how best to insure their destruction before they become scattered in the surface soil.

Sandwith says "cleanliness alone is required," but this is not enough. Of course, washing the hands before eating would prevent a certain number of infections, but if we remember the possibilities of infection through the drinking water and in the use of raw vegetables, to say nothing of the theory which Looss has proven, of infection through the skin, it can readily be seen that washing the entire body several times a day would not suffice.

The first step, the all-important step, is toward the destruction of the eggs and larvæ. It is well known that the embryos can not live without air. In view of this fact, Sandwith[1] suggested that infected villages should be compelled to dig trench latrines outside the villages, to use the latrines alone, and to cover them daily with earth. Thus the larvæ, deprived of necessary air, would soon die and cease to be dangerous, and as a result the disease would in time be stamped out.

Sandwith would also insure the death of the embryos by exposing the latrines to the sun's heat, as they have been known to live in shaded earth contaminated by feces for more than six months. Giles (quoted by Sandwith) recommends ploughing the infected surroundings of villages, so as to bury the embryos.

Stiles[2] has advocated practically the same thing as has Sandwith for the localities in our southern states where uncinariasis is known to exist. He suggests the use of suitable water-tight receptacles for feces, which should be emptied frequently; that the people should be taught the necessity of making use of these receptacles at all times, instead of defecating at any convenient spot, where the eggs hatch and the larvæ become disseminated through the surface earth.

This education of the people can only be accomplished by the family physician. No matter what care is taken or efforts made to enforce such regulations, the stamping out of this serious disease is going to be a difficult and tedious problem, simply because its occurrence is almost exclusively among the most ignorant of our people. The discharges might be burned or disinfected by chemical agents, but these methods are not practical in the country districts where uncinariasis prevails. To me the use of trench latrines would seem to be the most practical method of disposing of the infected feces, as it would necessitate very little trouble and no expense, items which would naturally appeal strongly to the people.

THE MEANS USED TO CAUSE THE EXPULSION OF THE PARASITE.

As an anthelmintic in uncinariasis thymol has almost entirely displaced all other remedies. (The credit of discovering the cure of ankylostomiasis by thymol seems to be due to Bozzolo, in 1880.—Sandwith.) The most popular method of its administration is as follows: The patient is given a purgative the day before, and is placed on liquid diet. Thymol is then given in 15 to 30 grain doses (1 to 2 grams) for four doses, at intervals of two hours. If the bowels do not move spontaneously in twelve hours after the last dose, a purgative is given. If an alcoholic solution of thymol is used, the majority of the worms are passed in six to eight hours after the first dose. Therefore, the stools passed within this time are the most important to examine for the parasite. If alcohol is not used they are seldom seen earlier than twelve hours after the first dose.

Sandwith has found that 4 grams (3i) given in two doses of 2 grams (30 grains) each at 8 and 10 a. m. respectively, are quite as efficient as the use of 6 or 8 grams given in three or four doses at intervals of two hours, and are less likely to cause the symptoms of collapse. He also omits the primary purge as unnecessary and conducive to exhaustion, and gives a dose of sulphate of magnesia or castor oil two hours after the second half of the thymol. It has been found best not to repeat the treatment more frequently than once a week unless there should be some specially urgent reason for a rapid expulsion of the parasites. This method and dosage, I think, will be found most satisfactory.

The fact that thymol is poisonous must not be lost sight of, and the patient should be carefully watched. Some authors have cautioned against the use of alcohol, ether, turpentine, chloroform, oil, glycerin and certain

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

1. Observations on 400 Cases of Ankylostomiasis, 1894.

2. Report on the Prevalence and Geographical Destruction of Hookworm Disease in the United States, 1903.

alkaline solutions during the administration of thymol because of its solubility in these media, thereby increasing the danger of rapid absorption and consequent poisoning. Other writers, however, advise the use of alcoholic stimulants, on the ground that the depressing effect of thymol is best combated by this remedy. No less an authority than Sandwith says: "Warned by the death of at least one of my patients immediately after digesting the thymol, I have always administered to feeble men 25 grams of brandy with each 2 grams of thymol, with the happiest results."

Stiles and Pfender in 1902 performed a number of experiments on dogs with thymol in various forms. From these experiments Stiles concludes by saying: "I am afraid of the use of alcoholics per os during treatment, and in the case of weak patients I should be more inclined to use a stimulant hypodermically than run the risk of dissolving the thymol too rapidly, or in too great quantity at one time."

Since thymol is the accepted anthelmintic in the treatment of uncinariasis, and as there seemed to be some difference of opinion as to the safety of its use in alcoholic solution, I instituted a short study of its action on dogs. I regret to say that time did not allow of as complete an investigation as I would have wished before the presentation of our conclusions before this Association. I hope, however, that a few facts of value have been determined.

The work has been carried on by E. E. Butterfield, a fourth-year medical student in the Columbian University and pathologic interne at Garfield Hospital, to whom I wish to express my thanks.

EXPERIMENTAL WORK WITH THYMOL.

Thymol was administered in powder, in alcoholic solution, rendered bland by the solution of olive oil, and hypodermically. Space does not allow of a discussion of previous observations upon the physiologic action of thymol; it suffices to say that our results did not agree in all respects with those of other investigators.

Thymol given in dry powder in small doses (2 grams) caused salivation, and later slight diarrhea. No marked or constant effect upon the temperature, pulse or general condition. Large doses (5 to 20 grams) cause profuse salivation, later vomiting, anorexia, disinclination to move unless aroused, diarrhea and slight elevation of temperature (0.5 F. to 1.0 F.), the latter appearing six hours or longer after the dose and lasting from twenty-four to forty-eight hours. Prolonged feeding in ascending doses of 2, 3, 4, 5, 6, 7, 8, 9, 11, 14 and 20 grams during four weeks caused no loss of weight, the weight of the dog on which this experiment was tried having risen from 22 to 26 pounds during the course of treatment. Eleven grams of the dry thymol is, apparently, not a dangerous dose to dogs of 22 pounds or more, if given carefully and after a meal. Four dogs were used in these experiments without a death.

Thymol Given in Alcoholic Solution.—Alarming symptoms immediately following the administration of the alcoholic solution of thymol to dogs, seem to be almost always, if not invariably, due to aspiration of the irritating solution into the lungs. In seven dogs to which an alcoholic solution of from 2 to 10 grams was given an extensive consolidation of lung tissue was the only significant lesion.

If aspiration of the alcoholic solution of thymol occurs the symptoms are immediate. In a few seconds the dog staggers, seems unable to stand, and in a few minutes develops general convulsions with unconsciousness. The temperature falls 1 to 3 F., pulse and respiration become rapid, pupils are widely dilated, and respond sluggishly to light. Convulsions last from five to fifteen minutes after consciousness is regained, the temperature rises slowly, and in from six to twenty-four hours reaches a point 1 to 2 F. above the normal. This elevation persists for a number of days. A persistent cough develops, a fremitus may be felt over the lungs, and râles are heard. If recovery takes place the dog regains his appetite in one or two days, the cough gradually abates and the temperature falls to normal. This occurred in two out of seven cases. In some cases there is persistent cough, elevation of temperature, loss of appetite and emaciation which would probably end fatally if allowed to do so. Three out of seven presented these symptoms, but were killed on the third to the tenth day after dosage, extensive lung lesions being found at the autopsy. Of the remaining two, one died almost immediately, the bulk of the dose having entered the lungs, none being detected in the stomach (the stomach tube had accidentally entered the trachea). The other, though not very sick, was killed four hours later to ascertain the early changes in the gastrointestinal tract.

Of the seven dogs experimented on, two recovered, and at the end of three weeks were apparently well, save for a slight cough; three would probably have died; one died; the remaining dog would undoubtedly have recovered, as the lung lesions were not extreme.

In conclusion it may be said that doses of 2 grams or more in alcoholic solution are unsafe for dogs, owing to a tendency to aspiration pneumonia.

Thymol in Alcoholic Solution Rendered Bland by the Addition of Olive Oil.—To avoid the irritating effect of the alcoholic solution, the drug was dissolved in alcohol, and enough oil added to render the mixture non-irritating, as tested by taste. Four grams were then given successfully to dogs of 16 to 17 pounds, without depression or fall of temperature. Six grams were given to a 17-pound dog, with a resulting fall of 2 degrees of temperature four hours after the dose was given, and lasting for six days, with depression, anorexia, diarrhea with bloody stools, emaciation (8 pounds lost) and coldness of the surface and extremities.

The autopsy, performed six days after the dosage, showed extensive subacute gastrointestinal inflammation with only two pea-sized areas of congestion at the base of the left lung.

Conclusions: Doses of 2 to 4 grams of thymol in alcoholic solution rendered bland with oil are safe for dogs of 17 pounds or more.

Thymol Hypodermically.—One 16-pound dog was given an alcoholic solution hypodermically to determine whether any toxic symptoms would develop from this manner of administration.

Ten c. gm., 0.20 gm., 1.00 gm. and 1.00 gm. repeated were given at intervals of one or two days without any apparent effect, except inflammatory swelling at the site of injection. Autopsy was performed one week after the last dosage. No pathologic lesions were found, except congestion of the lungs, which may have been produced during the process of anesthetization, which, in this case, was attended with considerable difficulty.

Autopsies on Eight Dogs.—Microscopic examination of the viscera of eight of the dogs to which thymol had been administered showed no changes which were not attributable to the local irritative effect of the drug. The liver, spleen, kidneys and heart muscle were normal. The changes in the lungs varied from intra-alveolar hemorr-

hage to bronchopneumonia in cases where aspiration had occurred. The condition of the stomach and intestines varied from mild congestion to marked inflammation, most intense after the administration of the drug in alcohol and oil; least intense after the dry. The probable reason why the inflammation was not so marked after the administration of the simple alcoholic solution was that it was so irritating that much of it was drawn into the lungs by the violent coughing it caused. In no instance were albumin or casts found in the urine at autopsy.

CONCLUSIONS.

1. The alcoholic solution of thymol is dangerous to dogs, even in small doses, chiefly because of its tendency to produce inflammation of the lungs by aspiration.

2. The alcoholic solution, even when rendered bland by the addition of oil, is dangerous in doses of more than 4 grams to dogs of 16 or 17 pounds, because of its irritative effect upon the gastrointestinal mucous membrane.

3. In dry powder the drug may be given to dogs in large doses without serious results, no depression, no fall of temperature.

4. Gram doses given hypodermically cause only local inflammation.

5. There is probably no danger in giving 2 to 4 grams, followed by 1 to 2 tablespoonfuls of brandy, to an adult human being, if followed in a few hours by a purgative such as castor oil or magnesium sulphate.

6. It is probable that the alcoholic solution obtained in this way would be more efficacious against the parasites, as seems proven by their much earlier appearance in the stools after the use of the alcoholic solution.

THE NUMBER OF DOSES REQUIRED TO EFFECT A CURE.

As to the number of doses of thymol which are usually required to effect a cure, I can not do better than to again quote Sandwith, who says: "In 184 patients I was able to prove the absence of worms by giving at least two, and sometimes more, doses of thymol after the last appearance of the parasite in the stools. The average number of doses required proves to be 2.6. Forty-two men were cured after only one dose, fifty-eight after two, forty-two after three, twenty-five after four, nine after five, and four after six doses of thymol. Two cases required seven attacks, and two others eight."

In my own case, after giving thymol at least nine times in a period of nine weeks in two doses of 2 grams each, separated by two hours, and followed by a purgative, there were found at the autopsy twenty-nine worms in the small intestine. This serves as a warning that in some cases the parasites are extremely difficult to exterminate, and require a prolonged course of treatment. The stools should be examined weekly for eggs, and as long as they are present the thymol treatment should be continued.

As to the resulting anemia and debility, a general tonic treatment with iron and abundance of good food and fresh air are indicated.

1323 New Hampshire Avenue.

DISCUSSION

ON PAPERS OF DRS. STILES, SMITH AND CLAYTOR.*

DR. W. G. HARRISON, Talladega, Ala.—After hearing Dr. Osler speak on this subject in his wards I felt sure that I saw some cases that were affected with hook-worm disease. When I came home a physician called attention to some suspicious cases at the Deaf, Dumb and Blind School. Several cases were found at the time the state medical association met with us, when Dr. Stiles was our guest. He confirmed the diagnosis in one of the four cases. A microscopic study of the case was not made until the early part of the last week. It was my purpose to treat the case with thymol, but at the suggestion of Dr. Stiles we gave them one or two remedies before resorting to thymol. These children were all in the schools. The youngest was 7 and the oldest only 18 years old. All were extremely anemic. No blood counts were made. Hemoglobin in the lowest was 25 per cent., in the highest 43 per cent. We were careful to make an accurate temperature record. The temperature of each of these patients was not much elevated. In four it was over 100 F., in three between 99.7 and 100 F. In only one was I able to demonstrate the malarial organism, so they could not have been due to latent malaria. In all cases there was a heart murmur, in three a systolic, in four an aortic. In four out of seven cases there was a marked pulsation of the vessels of the neck. It is rather an interesting point that Dr. Stiles himself recognized the disease in whites, but said he was not sufficiently familiar with its characteristics in the negro to recognize it. It was stated that it was likely one of the pupils would be affected with the hook-worm, and many students were examined and hook-worm disease found. Subsequently, in one of the schools, being unable to pick out the likely subjects, I asked the superintendent if there were any who appeared to be especially lazy, or any pupils who would not play, who would not take exercise, or frolic, or run or jump. He answered: "Yes, I have two boys who are so lazy that I can not get them to do anything." I examined those two and found the eggs in both. Three out of the seven cases I examined were among the blind. I saw two cases among the mutes. The peculiarity about the eyes was noticed. I had heard Dr. Welsh speak of the "stare." As soon as we were inside I said: "Doctor, I guess you will find the stare." Subsequently we went through the carpet factory and found in three out of seven cases the stare.

The treatment of these seven cases was as follows: Two were given four grains of calomel every three hours for four doses, and after a couple of days Epsom salts were administered. Twenty-four hours later the worms could be found in the stools. Then, for each patient, for two days, thymol was given in 15-grain doses at intervals of three hours. On the following morning there were found in the stools from 40 to 50 worms. The above was the treatment given in two cases. The third case was given 10 grains of salol every four hours for four days. No worms were found in 24 hours. In two days 10 grains of thymol were administered, and this patient passed 28 worms during the next 24 hours. In case four calomel, grains four, and santonin, grain one, were given every three hours until four doses were given. No worm inside of 24 hours. The next day two doses of 15 grains of thymol were given, and then there were passed between 60 and 70 worms. Case five fasted two days by accident, and this patient passed two worms before any medicine was given. That patient was given 10 grains of salol and 4 grains of calomel and 1 grain of santonin every three hours until four doses were given. This patient then passed 10 or 12 worms. On the succeeding day this patient was given 3 grains of thymol every three hours until three doses were taken, and on the following morning there was found in the stool 27 worms. Case six was given 15 grains of thymol every three hours for two days, and this patient passed a large number of worms, over 250, and probably four times as many more. Case seven had an incomplete record. He passed many worms.

DR. E. D. BONDURANT, Mobile, Ala.—My attention was first directed to the subject under discussion by a fellow practitioner in Mobile, Dr. W. T. Henderson, who told me of three cases which he had seen, and which from the peculiar edema shown he believed to be uncinariasis. The feces from those cases were submitted to me for microscopic examination, and in all of them I found the ova of uncinaria. Since then I have succeeded in interesting a number of my students and other doctors in the study of the disease, and have had a large number of fecal specimens sent to me for diagnostic examination. In this way I have already diagnosed more than

* The paper of Dr. Stiles appeared in THE JOURNAL July 18. The paper of Dr. Smith has not been furnished for publication.

fifty cases of uncinariasis in Alabama, chiefly from the counties of Mobile, Monroe, Escambia, Covington and Crenshaw, the greatest prevalence seeming to be in the sandy pine hill country west of the city of Mobile. In south Alabama there can be no question that the disease is more common on the sandy land than in the black lands or on dry formations. Uncinariasis is surely a very common complaint in our part of the world. It is rather a significant fact that in every instance in which uncinariasis has been suspected and fecal matter submitted for microscopic examination, I have been able to demonstrate the presence of hook-worm ova.

Being a neurologic specialist I have not had very great opportunity of studying the symptomatology and treatment of this disease, but during the past four months I have had to deal with uncinariasis as a complication or possibly causative factor in sundry cases of nervous disease. These patients, six or seven in all, have shown the anemia, listlessness and general mental and bodily enfeeblement already dwelt on by the authors of the papers under consideration, and all of them have been treated with thymol. The usual dose has been 60 grains, given in six capsules within two hours' time, preceded by calomel and followed by a saline. The results have been favorable without exception, numbers of worms being expelled and subsequent rapid improvement shown in the general condition of the patient.

Attention should, however, be called to the possible dangers of these large doses of thymol. One of my former pupils wrote me that he gave an 8-year-old boy 60 grains and came near killing him, the child passing into a conditon of coma with spasmodic movements and seeming at the point of death for hours; he was cured of uncinariasis, however.

Regarding the number of worms present, I know of one case in which a patient passed 953, and another instance, reported to me by Dr. Parker of Crenshaw County, in which "over 1,700 worms were counted, and there were more beside."

I have made careful examination of the blood in four cases, and in each one found a great diminution in hemoglobin percentage, with comparatively slight reduction in the number of red blood cells.

Now that Dr. Stiles has overwhelmed us with evidence and shown us how anybody can diagnose uncinariasis, we should not forget that the disease was recognized by Dr. Allen J. Smith ten years ago, when no one knew much about it, and its frequency was unsuspected.

Dr. C. A. Mohr, Mobile, Ala.—Unless one has had a case of uncinariasis one can not appreciate the great work accomplished by Smith and Stiles. We in Alabama can fully appreciate it, because they have been so plentiful there. For a long time we were unacquainted with the disease and were treating for this, that and the other thing, and especially for malarial anemia. In fact, the poor little devils have taken iron enough to build battleships, and without any effect on the anemia whatever. Only when our attention was drawn to the true nature of the trouble did we get any good results. The first case in Mobile was recognized by Dr. Henderson, and he made a diagnosis from the clinical symptoms only. The pulsations in the carotids, the intense anemia, the lowered amount of hemoglobin, the systolic murmur, etc., are all such striking symptoms. How the anemia is accounted for I am at a loss to say; I do not know whether it is due to the loss of blood, or whether it is produced by the toxemia, or possibly the secretions of the worms themselves. It is hard for me to believe from the amount of the anemia which is so intense as in chlorosis and the loss of hemoglobin, etc., that it is due to anything so far attempted in the way of an explanation. But I am sure that many cases of so-called "idiopathic anemia" will be found to be due to some parasitic disease.

Dr. G. W. McCaskey, Fort Wayne, Ind.—My experience is limited to but three cases seen in northern Indiana, occurring over one year ago. Two cases were in Syrians, and therefore imported, while the other was an American.

I wish to emphasize the importance of a routine examination of the feces, not only in hospital cases, as advocated by Dr. Stiles, but in private practice as well. For several years I have been in the habit of making this routine examination of feces in practically all cases. A number of writers think that it would not be necessary to do this; Ewald, Einhorn and others think it is not necessary. In 1895 I read a paper advocating this routine examination of the feces, and I have been keeping up such examinations ever since. It is not especially unpleasant; less so than sputum examination. My principal object in getting up to-day is to plead for this routine examination of the feces in all cases of obscure chronic nutritional diseases, in which, among many other things, important parasitic ova may be found at any time.

Dr. Claude A. Smith, Atlanta, Ga.—This disease is not especially confined to the sand belt; it is also found in the mountain regions. Through observations that have been carried on in Atlanta and adjacent territory, and especially by examination of students in the Atlanta College of Physicians and Surgeons and the Southern Dental College, I have traced the disease from the Carolinas to Texas.

Almost every country practitioner in the South sees every year any number of cases of anemia, and many of them of the profound type, which are often classed as malarial cachexia, and they have been treating these cases with quinin, iron, arsenic, etc., with only slight temporary improvement, and I have found many such to be cases of uncinariasis, and the treatment with thymol has given positive results, which were sometimes remarkable.

Since we have recognized in the South that this disease is so very common, the point which concerns us most at the present time is by what means does it reach the intestines. During my early observations I was inclined to the common belief that it is taken into the body in the drinking water, but later observations led me to the conclusion that the larvæ gain entrance through the skin of the feet, as first pointed out by Bently, producing the ordinary "ground-itch," which is so common in the South in the summer after a period of rainy weather. In fact, I have found that it is possible to locate cases of uncinariasis that you would not otherwise suspect by simply getting the history of the patient in regard to attacks of ground-itch, and I have found that every person who has had an attack of ground-itch within a period of seven or eight years has the uncinaria in his intestines.

My first experience with this disease was in December, 1901, when, on making a postmortem examination on a case which had died at the Grady Hospital in Atlanta, I found over 300 of the uncinaria in the small intestine, and on looking up the history of the patient I found that he was from Florida and had never been out of the South. As this case was evidently contracted in the South I naturally concluded that it must be endemic, and through the kindness of Dr. S. H. Green I obtained the stools of twenty convicts who work in the damp clay in one of the large brickyards near Atlanta, and of these twenty I found two cases of uncinariasis. These cases were reported by me at the session of the American Medical Association at Saratoga last year in the Section on Pathology and Physiology. Since that time I have found the disease to be so common as not to be practicable to keep a record of all cases.

The reason the full extent of the disease was not recognized sooner was because it is a disease of the country and not of the city, and it abounds under unsanitary conditions.

In regard to the systematic examination of the stools of all patients, as mentioned by Dr. Stiles, since the first case appeared at the Grady Hospital I have made a systematic examination of the stools of all patients, and during this time have found only three cases in the hospital. The rules of the hospital require that all applicants for admission must reside in the city, and this accounts for the small number. As I have mentioned before, you can locate the cases with a fair degree of accuracy by securing a history of the patient with reference to attacks of ground-itch within seven or eight years.

Dr. James B. Herrick, Chicago—I wish to call attention to the fact that although this is a disease of the tropics, we in the North should keep our eyes open for imported cases. This last year Dr. Capps of Chicago observed and reported

a case that came from Panama, and who reached Chicago after a prolonged stay in the hospital in New Orleans. In this case it is interesting to note the occurrence of 13 per cent. eosinophilia with very marked anemia, the large number of eosinophiles calling attention to the possible existence of an intestinal animal parasite.

DR. WM. BRITT BURNS, Memphis, Tenn.—I would like to refer to two cases which did not show uncinaria. The first case was an engineer who had been in a logging camp, sometimes having occasion to drive teams through lakes of mud. I had examined him a number of times for the malarial parasite, which I found, and thought he had a malarial cachexia. The man came to me in Memphis three months ago. He had fainted and I restored him in my office. He was then placed in the hospital. He had a very marked anemia. He did not remain long enough for me to make a complete blood count. The blood was found to contain the malarial parasite. He had no temperature at that time. The stools did not show uncinaria or other intestinal parasite. This patient had marked symptoms of sleepiness; he slept every time he sat down. He was an engineer at that time and when it was time for him to pull the cord attached to the whistle, on one occasion he raised his hand to pull the cord and went to sleep, and passed the station. He had some diarrhea alternating with constipation, and his bowels would gurgle, as he expressed it. He had some colic. The stools were white. I wished to get him for further examination, but could not.

The second case was a soldier from the Philippines who came to me with diarrhea, and he said that he had had it for some time, possibly a year. He had been in the hospital for six months. Coming on to the pathologic service six weeks ago I made several examinations of his stools. There were no malarial parasites found in the blood. The parasites that I found in the stools were of this character: (Blackboard demonstration.)

I would like to know more regarding the character of the stools in these cases of uncinariasis and of other parasitic diseases of the bowels. I would also like to know the condition of the spleen and liver, the skin and sclera, and also something of the pathology of the mucous lining of the gut, whether there is ulceration or much involvement.

DR. CHARLES WARDELL STILES, Washington, D. C.—With regard to ground-itch, I may say that this is exceedingly common in people affected with uncinariasis; but so far as I understand at present it is also found in people who have no hook-worm disease. I am informed by physicians of Georgia and Florida that practically every inhabitant of these states, except persons living in cities, have had ground-itch at one time or another. Undoubtedly uncinariasis infection may take place through the skin, as has been demonstrated experimentally by Looss of Cairo, Egypt. As to infection through the drinking water, I think this is possible, but the chances are that such method of infection is not so common as might be supposed, for the reason that the larvæ of hook-worms sink in water. Infection through cotton, as was suggested in connection with one case, I consider practically excluded on account of the dryness of the cotton.

Length of life of parasite: I have two cases where the parasites have lived six years, and one case six years and seven months, after the patients entered an orphan asylum.

Disinfection: I consider chemical disinfection of premises impractical. Yards may, however, be disinfected with fire, either by spraying burning oil or by scattering straw around and setting it on fire.

Number of parasites present: Dr. Harrison's case, which passed over 1,700 worms, is interesting, and so far as I know now holds the world's record. Ashford sent me about 1,400 worms from one case in Porto Rico.

Classification of the parasite: Dr. Smith has spoken of the validity of the American species. My studies on the anatomy of hook-worms have been interrupted, but it is now easy to foresee that the old genus *Uncinaria* will have to be subdivided. Worms like *Anchylostoma duodenale* and *A. caninum* form a distinct group characterized by the presence of recurred hooks in the mouth; these parasites should be classified in the genus *Anchylostoma*. The worms without buccal hooks, but provided with buccal lips, belong at present in the genus *Uncinaria*, but these forms may be divided into several subgenera, at least, which may eventually be given the rank of genera. The typical subgenus is *Uncinaria*, with *U. vulpis* as a type. Species with non-symmetrical bursa and with prominent buccal tooth, like *Uncinaria radiata* of cattle and *U. trigonocephala* of sheep, may be placed in Railliet's (1902) *Bunostomum*. *Monodontus* (Molin), 1861, should be based on *M. semicircularis*, and apparently presents, according to Molin, a symmetrical bursa with dorso-median ray of the usual type. *Uncinaria americana* seems to take a very isolated position, with its buccal capsule more or less similar to that of *Bunostomum*, but with a symmetrical bursa in which the dorso-median ray is of a very aberrant type. I believe we are justified in recognizing for this species a distinct subgenus (for which I would suggest the name *Necator*—a murderer), which may eventually be raised to generic rank. *Uncinara lucasi* is still different in certain characters, notably of the anterior end, and will probably call for the erection of a new subgenus. *Agriostomum* and *Characostomum* (Railliet), 1902, will probably stand as distinct genera.

The anemia: I agree with the view that it is difficult to explain the severe anemia and the nervous symptoms by the mere extraction of blood. In all probability the cervical glands of the parasites produce a poison which could be readily absorbed by the wounded mucosa of the intestine.

Diagnosis: As to the unpleasantness of a fecal examination, I frankly admit that I would much rather examine the feces than the sputum of a tuberculous patient.

Topography: I do not recall ever having stated that hook-worm disease is confined to sandy soils. What I claim is, that it is pre-eminently a disease of sandy regions.

Color of stools: The color of hook-worm stools is frequently a peculiar reddish brown, a quite different shade from anything I recall in connection with feces I have examined in Washington. Still, this color is not constant even in very severe infections. Nor is the blotting-paper test constant; in fact, it should never be relied on to the exclusion of the microscopic examination, for the chance of error is too great. I suggest the test simply as a convenient confirmatory test in severe cases for physicians in the infected district who are unable to make the microscopic examination. Blood in the stools is by no means constant. It does, however, occur.

DR. ALLEN J. SMITH, Galveston, Texas—It should be kept in mind, in comparing the group of cases which I have presented with the types of cases which have been mentioned in this discussion, that these instances represented a mild form, presented but few symptoms and were found in the course of a routine examination of a large group of persons undertaken because in some one or more of these persons it was certain the parasite existed. In the first and second of these cases the presence of an eosinophilia, found when searching for the malarial hematozoön, suggested the investigation of the stools for the uncinaria known to be present somewhere in the general group of students; and naturally the success of the search in these two early cases led to the thought of the value of the symptom as at least of suggestive force. In those cases of which I have records of the differential leucocyte count the proportion of eosinophiles ranges from 6 to 23 per cent.

There can be little if any doubt of the fact that one mode of acquirement involves the penetration by the embryonic worms in dirty water or in the mud adhering to dirty objects through the skin and tissues to their ultimate place of abode in the alimentary canal; while it is quite probable, too, that in many cases the entrance to the intestine is direct from drinking unclean water or eating dirty vegetables moist with damp earth. I do not feel that Dr. Stiles' view of the improbability of their transference by cistern water has included conditions which commonly prevail in the frequent over-ground cisterns found in many southern localities. There is easy chance for entrance of the ova to such cisterns by their being blown with sand and dust to the house-tops, whence they may be washed

by succeeding rains into the cistern. Sinking to the bottom of such receptacle they usually find what seems to me to be a not unsuitable surrounding for their incubation, providing they have retained their vitality, in the layer of sand or mud, mixed as it often is with charcoal commonly introduced into cisterns with a view of purification of the water; and as the faucets of these cisterns are placed close to the bottom it seems possible that the embryonic worms may be drained with the water used for drinking purposes or otherwise.

I also wish to lay some stress on the relationship which I believe may exist between this parasite and malaria. In six of the eight cases which I have mentioned there is a history of malarial complication, temporarily influenced by quinin, but invariably recurring after longer or shorter intervals. In several of these cases the demonstration of the malarial organism was unquestionable, but invariably was made only after repeated search and with more or less difficulty. While these malarial outbreaks were temporarily restrained by the administration of quinin, during the period of prevalence of the hook-worm in the intestine the malarial recurrences persisted indefinitely, the use of the quinin producing no permanent effect. All this ceased after the parasites were removed from the intestine, subsequent administration of quinin being promptly and permanently followed by the disappearance of the malarial symptoms. It might be suggested that in an indirect way the intestinal parasites have an influence in bringing about a persistence of the malarial infection—probably by lowering the natural powers of the system of the host in reaction and antagonism to some small residuum of the malarial infection after partial destruction by quinin, so that subsequently that residuum more surely may increase to a degree capable of producing the recurrence noted in such cases. With the removal of the worms there would seem to return the natural resistive influence of the body, and this joined with the potency of the quinin leads to complete and permanent destruction of the malarial infection. Doubtless there are other explanations possible for what in my experience is a very real relation of the character mentioned; but the idea suggested does not seem improbable. In such cases of an apparently malarial infection, with few organisms ordinarily recognizable, and these often missed, and with an irregularly recurrent type persisting after the use of quinin (although the latter may have been temporarily beneficial), I would urge that investigation be made for a possible complication by uncinariasis. If the latter be recognized I am confident that the experience I have mentioned may be repeated, and that by first removing the intestinal parasites it will be found that a difficult and persistent malaria will become readily amenable to the ordinary administration of quinin. It adds but little difficulty to the labor of diagnosis. The hook-worm egg is one of the most easily detected of microscopic objects in the fecal material; there is no complicated technic required in the examination of the material, and probably five minutes' attention as an average will suffice for the added work.

The relation between hook-worm diseases in man and in the dog is an item in which I am satisfied that I have publicly expressed mistaken ideas. In the discussion of this matter in 1901 before the Texas State Medical Association, I commented on the similarity of our human uncinaria and the dog hook-worm, and I expressed some question as to a possibility of identity as well as a possibility of the dog being an agent in scattering the parasites where man might acquire them. From the work of others as well as from the clear differences I have since learned to recognize between these parasites I fully realize the mistake into which my ignorance then led me.

I am satisfied, too, of another mistaken suggestion I made at the same time, namely, of the possibility of incubation of the eggs in the intestine of an original host, and thus a chance of permitting a slight infection to increase to a serious degree and to make itself permanent. While I am unable as yet to entirely set this idea aside as an occasional possibility, there is no doubt in my mind that it is essentially always untrue. That it is not impossible I would infer from the fact that occasionally the ova in very fresh feces are found to contain well-formed embryonic worms; and that rarely even in the ova within a gravid female worm an embryo may be found. Of course, too, the segmentation seen in the ova ordinarily is evidence of some procedure of incubation; and should the egg happen to be retained unduly in some groove or in a mass of mucus adherent to the mucous membrane of the intestine, it might on rare occasions develop into the freed embryonic worm. It is impossible for me to indicate why this does not ordinarily take place. I have noted in the incubation of ova in the fecal material that the process has proceeded more quickly and certainly at the ordinary room temperature than in the incubator at body temperature; and although there are probably other factors than mere temperature at work in this connection, it may be one element in restraining incubation in the intestine.

Dr. Thomas A. Claytor, Washington, D. C.—Regarding the elevation of temperature in these cases, it has been claimed that fever is unusual. I think, however, that this depends on the degree of anemia. In intense anemia, no matter from what cause, moderate fever of an irregular type is frequently seen.

Several of the gentlemen have spoken of symptoms by which they could diagnose uncinariasis—such as paleness of the skin, hemic murmurs, pulsation of the vessels of the neck, etc., which mean nothing but anemia, and hence are only suggestive. Without examination of the stools I do not believe a positive diagnosis can be made. It is an easy matter today to have such examinations made.

Regarding the dose of thymol to be administered, it is from 30 to 60 grains (2 to 4 grams). Sandwith, who has had a very large experience in the use of this drug, gives 30 grains at 8 o'clock, 30 at 10 and after two hours a purgative. In weak individuals he gives an ounce of brandy for every 30 grains of thymol.

It has been said that the American hook-worm is more readily gotten rid of than the old-world variety, because of the absence of hooklets in the former. In a case which I have reported two months' treatment with thymol failed to entirely free the sufferer from the parasites, though they were of the American variety.

The weekly treatment with thymol should be continued until the eggs disappear from the evacuations.

The Danger of Corrosive Sublimate Solution as a Vaginal Douche.—It is strange that at the present time many medical men are found who continue to use corrosive solution for purposes of postpartum douching in spite of the clear demonstrations that have been made of its unsuitability and of its dangers, and in spite of the introduction of many safe and efficient substitutes. The use of this dangerous poison for postpartum douching is not alone confined to general practitioners, but it is used and recommended by many competent specialists. A case is recorded in an American contemporary in which a patient, aged 33, who had miscarried at the fourth month, was given a single vaginal douche consisting of a quart of 1 in 1,000 corrosive sublimate solution. The next day she exhibited all the characteristic symptoms of sublimate poisoning—gingivitis, salivation, and diarrhea, the symptoms became rapidly worse, and she died a fortnight later. Of course, an antiseptic can not be condemned because it is carelessly used with fatal consequences in a single case, and, if corrosive sublimate had anything to very strongly recommend it, it would be foolish to do so, but what are its recommendations? It destroys metal instruments; it is a most dangerous lotion to leave about a house; it is decomposed and rendered useless in the presence of much albumin; it roughens the hands of the operator, and constringes the mucous membrane of the vagina and vulva, and so tends to encourage the occurrence of lacerations of these parts; and, as the case to which we have called attention shows, and as many other reported cases show, its use is by no means free from danger. The obstetrician who uses it himself is courageous, but the obstetrician who recommends it for general use to others—nurses or students—is foolhardy.—*Medical Press.*

SOLUBLE TOXIC SUBSTANCES IN AUTOLYTIC DISINTEGRATION PRODUCTS OF TYPHOID AND DYSENTERY BACILLI.

Up to the present time investigators have been able to isolate by filtration only toxins which go into solution in our liquid culture media. The best known examples of this are the diphtheria and the tetanus toxins. It has been to a degree disappointing that similar toxins could not be obtained from the typhoid, cholera and other organisms, as the possession of such toxins might make possible the preparation of antisera, to be used in the treatment of the diseases in question.

Recent work by Conradi, also by Neisser and Shiga, seems to indicate that some advance has been made in this direction. Conradi had previously observed that when certain organs (e. g., liver) undergo aseptic autolysis or self-digestion, through the agency of preformed intracellular ferments, substances were produced which hindered or prevented the clotting of blood *in vitro*. The same occurred in autolysis of yeast cells; and, furthermore, in both instances the end-product was bactericidal. These results led him and Drigalski to study the effects of autolysis of the dysentery bacillus cultivated from cases occurring among the German troops. The following method was used: An alkaline medium, consisting of 3 per cent. beef-water agar, to which 1 per cent. tropon was added, was solidified in large plates, and the surface inoculated with the bacillus. The plates were incubated for twenty hours at 37 C., the bacteria scraped off and put into tubes. A small amount of salt solution was then added and the tubes kept at 37.5 C. for twenty-four to forty-eight hours for autolysis to occur. The overlying slightly yellowish fluid was then drawn off after centrifugalization, five volumes of 0.85 per cent. salt solution added and then filtered through a Berkefeld candle. Subsequently, the filtrate was evaporated to one-tenth to one-fiftieth of the original volume. This constitutes a water-soluble toxin of which 0.1 c.c. kills a rabbit of two to three kilograms when injected intravenously. In the case of the dysentery toxin it is stated that at the autopsy the intestinal mucous membrane is congested and even ulcerated, showing a predilection of the toxin for this structure. A toxin of similar virulence was obtained from the typhoid bacillus by the same technic. It was found that prolonging the stage of autolysis to more than forty-eight hours gave a weaker toxin. The technic used by Neisser and Shiga was similar. They worked particularly with the typhoid bacillus. In addition to studying the toxicity of their product they directed their attention to its content of bacterial receptors. It developed that the filtrate had the power of binding agglutinin to a marked degree, and, furthermore, that by immunizing with it a serum was obtained which was highly agglutinating, and also bactericidal for the typhoid bacillus. A higher bactericidal power was obtained in this way than usually can be realized by immunization with the bacteria themselves. This proves satisfactorily that free receptors for agglutinin and the bactericidal antibody were present in the autolytic product.

The experiments of Neisser and Shiga, so far as reported, do not indicate that a true toxin was produced. The word toxin, as now applied to bacterial products, has a definite and exclusive meaning, referring to poisonous products of bacterial life, by immunization, with which a demonstrable antitoxin is formed. The antibody formed by immunization with the filtered autolytic product was a bacteriolytic one—an amboceptor, while antitoxin is a uniceptor. It does not appear from this work that a body corresponding in structure to other known bacterial toxins was found. Further study may show that such a toxin is present.

This work serves to emphasize the fact that bacterial life in the body may not be parallel with that in culture media. It is probable that bacterial disintegration goes on at a rapid rate, and continuously in the body in such diseases as typhoid and cholera, setting free large amounts of toxic substances, while under ordinary cultural conditions this takes place to a limited degree. In justice to the French, especially Metschnikoff and his followers, it may be stated that they have long claimed that strong, soluble toxic substances could be obtained from the cholera and to a less degree from the typhoid organism. There appears to be a distinct field for research in this direction.

IS HYDROPHOBIA A PROTOZOIC DISEASE?

The causative agent of hydrophobia has been sought for most thoroughly, but, so far, probably in vain. It was the fruitlessness of his search for the organism of hydrophobia that led Pasteur to suggest that it might be due to an organism too small to be seen, even with the highest and best microscopes. It is generally stated, however, that the cause of hydrophobia does not pass through ordinary bacteria-proof filters which permit the ultramicroscopic viruses of several other diseases of unknown etiology to go through. Whether the non-filterability of the virus of hydrophobia is due to the large size of the elements to form union with animal cells, or to other causes, can not now be stated.

In these days, when discoveries of protozoan organisms in diseases of unknown etiology are made with startling frequency; when, if everything claimed comes true, the causes of smallpox, of vaccinia, of yellow fever, and of dengue (to say nothing of cancer) have just been discovered, it is not at all surprising to read that a peculiar

"protozoan organism" has been found to occur constantly in the nervous system of hydrophobic animals, especially dogs and rabbits. This announcement is made by Negri,[1] an assistant to Golgi in the laboratory for general pathology and histology in the University of Pavia. The appearances on which Negri bases his claims are easily brought out by ordinary staining methods in material fixed according to current histologic procedures. Hence his results are easily controllable. The "parasites" occur in the protoplasm of the larger nerve cells: in Ammon's horn, the cerebellum, the cerebral cortex, etc. They are of varying size and form, the interior containing smaller bodies, sometimes to the number of twenty or thirty. Negri regards these latter appearances as the result of reproductive processes, and declares, without hesitation, that he is dealing with living, "organized" formations, the probable cause of hydrophobia. He finds these "organisms" in the central nervous system of rabic dogs and rabbits, no matter the exact mode of infection. In the rabbit the "organisms" are smaller than in the dog; they make their appearance in the cells about the thirteenth or fourteenth day after inoculation; that is, shortly before the manifestations of the earliest symptoms. He has found these bodies in one case of human rabies. The investigations, so far, seem to limit the occurrence of such bodies as he describes to hydrophobia.

Are the bodies described by Negri protozoa? This question can not be answered positively, but it is unquestionably possible for degenerative and other changes in cells to produce structures that morphologically resemble certain stages in the complicated development of protozoa. This being the case, which no one will deny, we must seek for other evidence of the protozoan nature of structures like those described here than is found in a more or less superficial resemblance to protozoa. But such evidence is not forthcoming. Anything like complete developmental cycles has not been described. It has not been shown that the bodies studied are really living, independent, multiplying organisms. They have not been cultivated artificially, and a vast amount of work remains to be done before any definite opinion is permissible. Let us hope that the general appeal now being made to protozoa to shoulder the responsibility for causing so many destructive diseases whose etiology, so far, has escaped search, may not prove altogether in vain.

RESPONSIBILITIES AND DUTIES OF HOSPITAL PHYSICIANS AND SURGEONS.

The increase of smaller hospitals, strikingly shown by the number and variety of official connections still occasionally attached to the name of a more or less prominent physician or surgeon, has been commented on frequently in these columns. The layman of intelligence is rapidly acquiring a taste for the environment and order pervading a hospital. Birth of these smaller institutions is by no means confined to the large metropolis; individual or corporate enterprise has foreseen their need in many obscure but thriving communities. For the care of the ill and injured in this manner, resident and attending staffs have multiplied, considered in the aggregate, to an extent realized by few persons. One pleasing consequence of this is that post-graduate hospital training is accessible to many more than heretofore.

No uniformity of procedure or government of the medical forces of this great class of minor institutions exists, scattered as they are among divers religious denominations, mines, railroads and large manufactories, or organized with capital invested for direct or indirect profit. The responsibility to the public for their conduct is at times assumed by a single member of the profession; sometimes it is undertaken by a wealthy industry, or it may rest with some sectarian or educational organization. No doubt the average attending physician and surgeon feels that the essential duty of his hospital connection is the immediate amelioration of human suffering; another duty of great importance, but as yet only insufficiently fulfilled, is the training of younger men.

The service of internes in some hospitals is too long, the number receiving such training thereby being limited. In many hospitals the service is not a graduated one; in others the training is narrowed to certain branches of medicine. In a large number the amount of labor and the few to perform it precludes anything except sordid drudgery. It is well known that the responsibility for evils of this kind in hospital management and the power to amend them rest with the medical board or attending staff, yet the absence of any coordinate effort to correct these is as noticeable in numerous conspicuous instances as is the failure of conjoint action in other matters awaiting organized action. Commensurate with this failure is the absence of anything like general effort to properly instruct their subordinates and to form little centers for the diffusion of knowledge.

The mechanical nature of the duties of internes in some hospitals might excite the suspicion that the surgeons or physicians do not desire to transmit to others the facility of diagnosis and skillful technic to which they owe some eminence. The need of completing a large number of operations in a given period or of seeing many patients hurriedly not only excludes opportunity for instruction, but is conducive to an irascibility of temperament, rendering the labor of others purely perfunctory. The young graduate is left to acquire or "absorb" what knowledge he may; certain methods of address and mannerisms of dealing with the laity, serving poorly for the subsequent attainment of a lucrative practice, may be acquired as well.

It is emphatically an error to suppose that the entire duty to the recent graduate is discharged by affording him opportunities of contact and association with leaders in medicine. The obligations of instruction and precept, of delicate hint and question, and, best of all, of

example, are but poorly realized and inadequately met in many hospitals. The culpability of such defects is enhanced many times by the realization that conditions do not exist where medicine, in the broadest sense, can be taught as well as at the bedside and operating table. To such failures of attending-men as individuals are attributable the poorly constructed and incomplete records, and the entire absence in many hospitals of any progressive spirit of scientific inquiry in the "house staff." Clinical instruction in small classes is as acceptable to recent graduates as to undergraduates; its retroaction would be wholesome for many.

That some men have realized such opportunities is shown by the detailed examinations and careful clinical records; by the rapidity with which intelligence of their arrival is spread through the hospital; by the reverence for and retention of their teaching, and by the loyalty they enjoy from the constantly increasing number completing service under their enlightened supervision. It will be denied by no one that there is room for improvement in the directions indicated in the foregoing, improvement as applicable to the small as to the large institutions.

THE INFLUENCE OF THE DWELLING IN THE DEVELOPMENT OF TUBERCULOSIS.

While the rich are not immune, and do not escape its ravages, tuberculosis is, in a large measure, a disease of the poor, and this is so because with the rich there is generally intelligence and a knowledge of hygienic measures and the means to provide them, while with the poor the usual accompaniments are too often ignorance, indifference and neglect, together with all of the other disadvantages that attend poverty. This fact has been established statistically wherever it has been investigated, and the studies, particularly of Flick in Philadelphia and later of Biggs in New York, have shown conclusively that there are certain districts in large cities and certain houses in those districts in which tuberculosis occurs for many years with almost uninterrupted continuity. An interesting inquiry on similar lines has recently been conducted by Professor Romberg and Dr. Gaedicke for the city of Marburg, and the results are recorded in the *Deutsches Archiv für Klinische Medicin,* 76 B., 4 u. 5. H., p. 309. An analysis of the figure shows that while among the 18,000 inhabitants of the city 197 (1.1 per cent.) were victims of pulmonary tuberculosis, about four-fifths of the cases occurred in the poorest fifth of the population. The percentage of cases was 4.7 per cent. in the poorest fifth, as against 0.2 per cent. among the better class. The lesson to be learned from this fact is that measures for the eradication of the disease must be directed to the poorer class. It was further found that 34 per cent. of all of the cases occurred in 2.6 per cent. of the entire 1,503 dwellings in the city, while 59.2 per cent. of all of the cases among poor occurred in 33.6 per cent. of the houses occupied by them. No definite relation could be discovered to exist between the situation, mode of construction and number of occupants of the houses and the frequency of the disease. While filth alone was not responsible for the presence of the disease, the latter was not found in clean dwellings. Nothing could be established as to the individual predisposition of the occupants. The cases in children and a study of individual cases would seem to lead to the conclusion that in a large proportion the disease must be referred to infectious influences. It has been shown that a single inoculation with tuberculosis is often followed by no evidence of disease. Repeated inhalation of tubercle-bacilli, however, through association in a filthy dwelling with a person or with persons careless with respect to cough and expectoration, is a most important etiologic factor. For this reason pulmonary tuberculosis must be looked on as a house disease, especially among the poor, and accordingly the best results in prophylaxis are to be looked for as a result of measures directed to preventing the spread of the infection through this channel.

But it is not altogether architecture that is responsible for the greatly excessive incidence of the tuberculosis among the poor. There are other causes from which they suffer far more than do those who are above them in worldly means. Among these are alcoholism, ignorance of hygiene, as already intimated, as well as their inability to mend matters in their defective dwellings with their proletarian tendencies, even if they had the knowledge and the will.

We talk much about the housing of the poor, but it is a fact also that the housing of the moderately well to do needs a consideration that it does not adequately receive. Many of the moderately high-priced flat buildings in our crowded centers of population are structurally, so far as fresh air and light are concerned, positive temptations to disease. That they are not more fatal is due in part to the fact that children are to a large extent excluded in their tenantry, and they are, therefore, less crowded. In either way, however, they are direct factors in the present problem of race suicide.

CLASSICAL APHASIA.

One of the Emerson anecdotes that came out during the recent celebration of the hundredth anniversary of the Concord philosopher's birthday, seems to deserve a place in the memory of American medical men, because it is such a striking illustration of aphasia. Emerson, who had been the greatest master of words in his generation, lost the power of speech as the result of a brain lesion, though he retained much of his power to think with the vigor and distinction of earlier days. A contributor to the June *Atlantic* illustrates his aphasic condition by retelling the story Emerson told of a carriage ride during which it rained. "After a while the—the—the—the—How do you call what stores up water till it is suddenly—suddenly—what shall I say? Not squeezed out?" "A sponge?" his hearer suggested. "No, no," with the sweetest of smiles and a sweeping motion of the hand up to the sky. "The clouds, perhaps?" was the next suggestion. "Yes, the clouds began to roll up

and threaten rain. I had forgotten to take with me my—my—my—By the way, what is it that people always borrow and never return?" "Umbrella?" was suggested. "Yes, umbrella," and so on with other lacunæ in the conversation. The contributor notes: "While, as everybody recognizes, the inmost philosophical essence of the umbrella was thus intellectually grasped, the mere empirical designation of its silk, stick and whalebone would not turn up." The story illustrates very well the merely mechanical hindrance that aphasia is to the expression of thought, though in severe forms it may apparently deprive even a vigorously thinking mind of much of its capacity for properly expressing itself. It is this very feature which constitutes the essence of aphasia. Yet this is often supposed to indicate, even by the medical man, that there must be some impairment of the mental processes behind, not seldom to the perversion of justice in the making of wills and the regulation of business affairs.

IS MEDICINE ATTRACTIVE TO SCHOLARLY MEN?

Professor Thorndyke,[1] of Columbia University, New York, has traced the careers of 5,283 college graduates (1840-1900) who were elected to the Phi Beta Kappa, membership in which is a recognized mark of scholarship. The object in doing this was to learn whether any given profession is gaining or losing in attractiveness to the type of men represented by membership in this fraternity. In the first place Professor Thorndyke finds that there is a remarkable uniformity in the percentage of Phi Beta Kappa men entering the leading professions, namely, from 64 to 68 per cent. for 1840-1900. But the percentages entering the various professions have been far from constant; thus the number taking up law was nearly twice as large in 1890-1894 as in 1840-1860. There has been considerable variation, too, in the number that have taken up teaching as a profession. The Phi Beta Kappa man was "three times as likely to become a clergyman in the middle of the century as he is to-day." The ministry has lost steadily in its attractiveness to this kind of man, and this loss has been quite uniform throughout the country. It is interesting to note that Professor Thorndyke's statistics show that medicine has not been a popular profession with what he calls scholarly graduates. From 1840-1885 the percentage ran from 8 to 4; from 1885 to 1894 7.5 and 7 per cent. entered medicine. He suggests that the gain after 1885 is due to the advance of medicine to the dignity of a science, and to the introduction into the colleges of elective courses in science. Professor Thorndyke's forecast of the future is as follows: "The future will probably witness a steady gain in medicine, a slight gain in teaching, a rapid but unstable gain in law, and a continued decline in the ministry." At the present time law and teaching get the lion's share of the scholarship of the country, as represented by the careers chosen by the members of Phi Beta Kappa. We believe that the indications point to a steady increase in the number of scholarly men choosing medicine for the field of their life-work. The opportunities for research, specialization and beneficent activities certainly can not but draw to medicine increasing numbers of high-minded college students. The inherent attractiveness of medicine because of the altruistic nature of its functions will be reinforced markedly henceforth by the rapidly growing opportunities to study medicine under propitious conditions, and by the favorable attention it is now receiving at the hands of our best universities on the one side, and of our wealthy philanthropists on the other.

1. Century Magazine, May, 1903.

FURTHER OBSERVATIONS IN REGARD TO RADIUM.

The possibilities of such mysterious forces as those possessed by radium present an attractive field of speculation for the physician. May not the radiant energy emitted by radium possess pathogenic as well as curative, destructive as well as stimulating, powers on cells and cellular processes? Perchance, it may be forces of this kind that upset physiologic laws of cellular activity, and lead to abnormal proliferations of various kinds? But questions of this kind are not yet ripe for discussion. Actual experimental studies must furnish the necessary basis of facts from which it may be permitted to draw further deductions. Danysz[1] found that radium destroys the skin of guinea-pigs and rabbits, but subcutaneous and muscular tissue do not seem so sensitive as skin. The nervous tissue is also sensitive to its action. A sealed glass tube with salts of radium placed against the skin over the spine is followed by death in young animals. In older animals the osseous tissue seems to protect the spinal cord against the radiations. The effects of rays of radium on bacteria have not been studied extensively as yet, but both Danysz and Bohn show that various larvæ and embryos are profoundly modified in their growth, many being killed when subjected to the radiations; others developing into monstrosities because of unequal stimulation. Bohn further finds that radium exercises an especially intense action on tissues or cells in proliferation; non-fertilized eggs may undergo more or less parthenogenetic development and give rise to atypical formations. It has been found, too, that in animals whose skin was burned by the rays, the hair, in some cases, appeared to be forced into rapid growth. It seems that various effects are obtainable, depending on the tissue or cell exposed, as well as on the quantity and quality of the rays. Further experiments, no doubt, will yield even more interesting and conclusive results. We have commented on the announcement that in Vienna cancer has been cured by means of radium. In this particular direction much work will surely be done, and we may expect interesting developments.

THE VALUE OF EXPERIMENTAL STUDY OF TRANSPLANTABLE TUMORS.

The study of malignant tumors by the usual methods hitherto in vogue has not yielded many results of fundamental importance. A serious drawback to this study is encountered in the non-inoculability of human tumors in animals. The occurrence in certain animals of transplantable tumors furnishes the investigator with welcome opportunities to institute various lines of experimentation looking, for instance, to the production of immunizing and curative substances. Thus Jensen[2] of

1. Compt. rend. de l'Acad. des Sciences, 1903, cxxxvi, 461-4.
2. Centralbl. f. Bact., 1903, xxxiv, 28-34, 122-143.

Copenhagen was able to work with an inoculable, spontaneous tumor in a white mouse. He has carried the experimental inoculation through nineteen generations, and other experiments have been made with a view to producing active as well as passive immunity—at the same time as the tumor cells have been subjected to various procedures calculated to throw some light on their properties. This tumor occurred originally subcutaneously, and was in structure a carcinoma, which character it subsequently maintained. Subcutaneous injections of material rubbed up and suspended in salt solution were followed, as a rule, in fourteen days or so by the development of a small nodule at the site of injection, which slowly increases in size up to 15 to 20 grams. Metastases seem not to have occurred. During two and a half years successful transplantation has been made, as stated, through nineteen generations, about 50 per cent. of the animals used proved susceptible. As in the experiments of Leo Loeb, Herzog, Moran, it here also concerns a genuine transplantation, and not a true infection, because Jensen, who studied this point with the greatest care, found that simple crushing of the tumor cells before injection gave always negative results. Living cells must be transferred in order to secure success. These and the other experiments with transplantable tumors lend no direct support whatsoever to the parasite theory of tumors. In reality, successful transplantations in the same species are, so to speak, equivalent to the development of metastases in the individual. Jensen found that the tissue of the tumor he followed through so many animals remained alive for about eighteen days at a temperature of 1 to 3 C., at room temperature for about twelve days, but at bodily temperature only for twenty-four hours. The cells were killed by heating for five minutes to 47 C. and by exposure to —20 C. for twenty minutes. The tumor tissue was also killed readily by intense light, but the rays have the power to penetrate only for a small distance into the depths of the tissue. Here are examples of the procedures to which transplantable tumors may be subjected, with the view of laying bare some of the secrets of the tumor-producing forces: Carcinoma in mice appears to offer good starting points for valuable studies of this kind, and it is very desirable that examples of tumors in this and other animals be placed at the disposal of competent pathologic laboratories. Physicians who may come to know of tumors in mice, dogs, cats, etc., will render science a service by securing such animals for experimentation under the most favorable conditions.

Medical News.

CALIFORNIA.

Aged Physician Injured.—Dr. Malek A. Southworth, San Jose, while driving across a railway track at Wayne, was struck by a train and sustained severe scalp wounds and contusions, and the fracture of two ribs.

Dr. Landis Released.—The Supreme Court has decided that Dr. Amos J. Landis, Chico, convicted of forgery and sentenced to serve seven years in prison, was indicted by a biased and prejudiced grand jury, and given a partial trial; and, therefore, that the judgment of the lower court is reversed.

Bogus Inspector Convicted.—H. G. Myers, Stanford, who traveled around the country representing that he was commissioned by the State Board of Health to examine women, was sentenced to imprisonment in the county jail for ninety days and to pay a fine of $200, the limit allowed by law.

Personal.—Dr. Charles F. Taggart, Los Angeles, chief surgeon of the San Pedro, Los Angeles and Salt Lake Railroad, has gone to Salt Lake City to arrange a hospital service for the road. ——Dr. Albert C. Rogers, Los Angeles, has returned from Europe.——Dr. Charles B. Brigham, San Francisco, had a paralytic stroke, July 10, and is lying seriously ill at his country place near Lake Tahoe.——Dr. Norman H. Morrison, San Francisco, sailed, July 16, for a tour of the Hawaiian Islands.——Dr. Thomas M. Hayden has succeeded Dr. George H. Aiken as president of the Fresno Board of Health.——Dr. John H. Meyer, San Bernardino, has begun his official work as county physician and superintendent of the county hospital, vice Dr. Samuel G. Huff.——Dr. and Mrs. Hoell Tyler, Redlands, have gone to Europe.

COLORADO.

Personal.—Dr. Anders J. O. Lof, Aspen, returned, July 17, from Vienna.

Illegal Practitioner Flees.—"Dr." M. E. McGrath, who was arrested at Denver, charged with practicing medicine without a license, has fled from the city, forfeiting his bond of fifty dollars.

Denver's Deaths.—In May 198 deaths were reported in the city and county of Denver, equivalent to an annual death rate of 13.57 per 1,000. Of these 62 were due to tuberculosis; 18 to pneumonia, and 11 to valvular heart disease.

Hospital Changes Name.—Following the consolidation of the city and county governments, the name of the Arapahoe County Hospital has been changed to the Denver City and County Hospital. The management of the hospital is now under Health Commissioner Dr. Augustus A. Clough.

Hospital Incorporated.—Drs. Samuel T. Quick, Albert W. Killgore and E. Stuver have incorporated the Fort Collins Hospital Association, with a capital stock of $50,000. Nearly all the physicians of the city are identified with the enterprise as stockholders, and as all physicians are guaranteed complete professional control of all cases they may send to the hospital, the undertaking is looked on with great favor, both by the profession and citizens generally.

ILLINOIS.

Maternity and Orphan Asylum.—Contracts have been let for a two-story building for the St. Vincent Maternity and Infant Asylum, at Park Ridge, to cost $20,000.

National Guard Appointment.—Dr. Arthur F. Wilhelmy, Decatur, has been appointed assistant surgeon in the Illinois National Guard, with the rank of first lieutenant, and assigned to the Fifth Infantry.

Healers Jailed.—Two alleged magnetic healers, who fleeced many citizens of Peoria and then levanted, have been captured in Omaha, and will be returned to Peoria, where they will be prosecuted on a charge of obtaining money under false pretences.

No Typhoid in Illinois River Water.—The commissioners appointed to investigate the condition of the Illinois River in the case of the State of Missouri against the State of Illinois, for alleged pollution of the Mississippi River, have been unable to find a single typhoid germ in the Illinois River.

Births and Deaths.—Circulars have been mailed by Secretary James A. Egan of the State Board of Health, to the physicians of Illinois, calling their attention to the new certificates of deaths and births, which they are required by law to fill out and return to the county clerk, and in Chicago and Peoria, to the Commissioner of Health, in the cases of births, and in the cases of deaths to the State Board of Health, except in cities where burial permits are issued. He accompanied the circular with sample certificates and with a circular issued by the United States census office on "The Relation of Physicians to Mortality Statistics." The new law is being very generally complied with.

Chicago.

Licenses for Infant Nurseries.—Two licenses and permits to conduct infant nurseries have thus far been issued by the city clerk.

Bequests.—By the will of the late Horace P. Taylor, $9,400 each is bequested to St. Luke's Hospital and the Chicago Baptist Hospital, to be used for endowing free beds.

Physicians in Collisions.—During the past three weeks Drs. Arthur R. Edwards, Frank W. McNamara, Louis A. Greensfelder

and Jacob Frank have suffered physically or financially by the collision of carriages in which they were riding, with other vehicles.

Fights Fine.—Dr. Frederick L. Orsinger has secured an injunction restraining the State Board of Health, Justice Chott, and his constable from causing his imprisonment or enforcing a judgment for $100 and costs secured against him for alleged violation of the medical laws.

Summerers.—Dr. E. Fletcher Ingals has gone to Connecticut, where he expects to spend the next two months rusticating, and incidentally learning to play golf.——Dr. Frank Billings is at his cottage at Mackinac.——Dr. Henry Hooper is spending his vacation at the Huron Mountain Club, Lake Superior.

Low Death-Rate.—A phenomenally small proportion of deaths among the aged is mentioned by the Department of Health, as one of the noteworthy features of a remarkably low July death rate for the week ended July 25. There were only 55 deaths among those over sixty years of age reported out of the total 513 at all ages, while the rate for the total—14.19 per thousand—is the lowest ever recorded for any July week in Chicago. For the 25 days of the month the rate is 14.69 per thousand as against an average July rate for the previous ten years of 17.64 per thousand. This decrease of more than 16 per cent. is to be attributed chiefly to the low and equable temperature of the month.

INDIANA.

Proposed Medical College Merger.—There is a movement in progress to form a union of the faculties of the Medical College of Indiana and the Central College of Physicians and Surgeons with a possibility of its consummation. There would then be but one medical college in Indianapolis, and it may become a medical department of the Indiana University, which is located at Bloomington. With a view to consolidation, a committee from each institution has been appointed to outline an agreement satisfactory to each interest.

Deaths in June.—There were reported 2,265 deaths, an annual rate of 10.9 per 1,000; 306 were under 1; 147 were 1 to 5; 60 were 5 to 10; 45 were 10 to 15, and 589, or 27.9 per cent. of the total were 65 and over. The consumption deaths numbered 306, the city rate being 1.7 per 100, and the county rate 1.3. Deaths from certain important causes were: Pneumonia, 124; diarrheal diseases, 75; cancer, 96; typhoid fever, 42; diphtheria, 15; scarlet fever, 7; whooping cough, 24; puerperal fever, 8; violence, 133, and smallpox, 4.

Diseases in June.—The monthly bulletin of the State Board of Health, shows that rheumatism was the most prevalent disease and that tonsillitis and bronchitis were respectively second and third in prevalence. Typhoid fever was fourth, having stepped up from seventh place in the preceding month. Smallpox was sixth, having fallen from third place. Diarrhea, as was to be expected, increased in June over May, yet dysentery and inflammation of the bowels show no increase. Diphtheria, pneumonia and influenza were very much less in June than in May.

Personal.—Dr. John G. Wishard and family, Indianapolis, start early this month for Persia, where Dr. Wishard returns as medical director of the American Presbyterian Hospital, Teheran.——Dr. Charles E. Laughlin, Orleans, has been appointed superintendent of the Southern Indiana Hospital for the Insane, Evansville.——Dr. Charles M. Eisenbeiss, Elkhart, recently appointed a member of the State Board of Health, has resigned as coroner of Elkhart County, and Dr. Fred N. Dewey, Elkhart, has been chosen in his stead.——Dr. Jehu Z. Powell, Logansport, has been appointed physician at the National Soldiers' Home, Johnson City, Tenn.

IOWA.

Drake's Cornerstone Laid.—The cornerstone of the new medical building for Drake University, Des Moines, was laid, July 10. General Francis M. Drake delivered the address.

Explosion in Physician's Office.—Dr. W. P. Hombach, Council Bluffs, suffered severe contusions, and Mrs. Hombach a compound fracture of the leg in an explosion of illuminating gas which had accumulated under the new office building of Dr. Hombach. The building was completely wrecked.

New and Enlarged Hospitals.—Burlington Hospital is to have an addition and a nurses' home erected, to cost $35,000.——St. Thomas' Hospital, Marshalltown is now almost ready to receive patients. The formal dedicatory exercises will be held later.——Charles H. Keck has given to Washington, to be used for a hospital, the residence of his deceased father. The property is valued at $10,000.

Personal.—Dr. Albertus J. Burge, Iowa City, has been appointed assistant to the chair of surgery in the University of Iowa.——Drs. Alphonse L. Hageboeck and Edward F. Strohbehn, Davenport, have returned from Europe.——Dr. Donald McCrae, Jr., Council Bluffs, has been appointed surgeon-major in the Iowa National Guard, and assigned to the Fifty-sixth Infantry, vice Dr. Gilbert L. Pray, Lake City, resigned.——Dr. Albert S. Rider, Donnellson, has been elected professor of pathology and bacteriology in the Keokuk Medical College, College of Physicians and Surgeons.

KANSAS.

Fire at Sanitarium.—Four lives were lost at a fire which destroyed Bonner Springs Sanitarium on July 16. The financial loss is estimated at $20,000.

Medical Department for National Guard.—A medical department has been organized in the National Guard under the command of Surgeon-General Dr. Henry O'Donnell, Ellsworth.

Superintendent Assaulted.—Superintendent Thomas C. Biddle, M.D., of the Topeka State Hospital was assaulted by two attendants, who were afterward dishonorably discharged from the institution.

Meffert Appeals.—Dr. William M. Meffert, Emporia, whose license was revoked June 12 on account of gross immorality, has taken an appeal to the United States Supreme Court, and meanwhile continues to practice.

License Revoked.—The State Board of Medical Registration and Examination revoked the license of Dr. Robert E. Gray, Garden City, on the ground of immorality and unprofessional conduct in the case of Irma Brown, of whose murder Gray was acquitted in Chicago in 1902. Gray says that he will appeal to the Supreme Court.

KENTUCKY.

Dr. Bodine Out of Danger.—Dr. James M. Bodine, Louisville, on whom an operation was performed July 1, is now reported to be securely convalescent.

Commencements.—The medical department of Kentucky University conferred degrees on a class of 57, July 3.——Kentucky School of Medicine graduated a class of 56, July 8. The doctorate address was delivered by Dr. William H. Wathen.

Personal.—Notre Dame University, at its recent commencement, conferred the degree of LL.D. on Dr. Martin F. Coomes, Louisville, editor of the *American Practitioner and News*.——Dr. Cleon C. Owens, Frankfort, was painfully injured by a fall while climbing cliffs on the Kentucky River.——Dr. William S. Yazell has been elected health officer of Maysville.——Dr. John C. Cassidy, Eminence, has been elected secretary, and Dr. Pink H. Crutchfield, Bethlehem, president, of the Henry County Board of Health.——Dr. Rolla H. Alexander, assistant physician at the Eastern Kentucky Asylum for the Insane, Lexington, has resigned.

Requirements Must Be Enforced.—The requirements governing entrance to the different medical colleges of Kentucky are to be rigidly enforced, according to action taken at a meeting of the executive board of the State Board of Health in Louisville. The penalty of being refused recognition was provided, to compel all reputable institutions to adhere to the rules. This action resulted from a conference between the deans of the medical colleges and the members of the State Board of Health held May 22. It was alleged at that meeting that many medical schools in Kentucky have at various times admitted students in violation of published requirements and have offered them private inducements to take up the study of medicine. It is said that these allegations were confirmed.

MASSACHUSETTS.

Milford Hospital Dedicated.—Milford has a new hospital built through the generosity of Hon. Eben S. Draper, the manufacturer of Hopedale, at a cost of more than $60,000, which was dedicated by appropriate exercises, July 24, in the presence of more than 15,000 people.

State Mortality.—For the week ended July 11 40 cities and larger towns of Massachusetts reported a mortality of 675. Of these 254 were of children under 5 years; 187 were from infectious diseases; 51 from acute lung disease; 61 from phthisis; 5 from diphtheria; 7 from scarlet fever, and 95 from diarrheal diseases.

Floating Hospital Busy.—The Boston Floating Hospital is as busy as usual. The first ten days of its service showed 100

different patients cared for, 60 of whom were permanent patients. The number of ileocolitis cases has been much smaller than usual, while the number of marasmus cases has been larger than usual. Six or eight sick babies are refused each day on account of lack of accommodations.

Boston's Deaths.—The mortality record for the week ended June 25 shows a little gain, 188 deaths were reported, equivalent to an annual death rate of 16.25 per 1,000. Of these pneumonia caused 8; pertussis, 2; heart disease, 19; bronchitis, 2, and marasmus, 1. There were reported of diphtheria, 35 cases, with 4 deaths; of scarlet fever, 20 cases; of typhoid fever, 21 cases; of measles, 20 cases, with 2 deaths, and tuberculosis, 20 cases and 28 deaths.

NEW JERSEY.

Lacks Authorization.—It has been discovered that the bill appropriating $200,000 for a state tuberculosis sanitarium is not a law, because the act of authorization was overlooked, or purposely omitted.

Personal.—Dr. C. Radcliffe Johnson, Atlantic City, who recently accepted an appointment as medical missionary to the Philippines under the auspices of the Episcopal church, and is to be stationed at Manila, sailed from San Francisco June 11.

Isolation Hospital Burned.—The building erected in Orange as an isolation hospital for smallpox, in 1901, was burned July 2, with all its furniture and medical supplies. The loss is $2,000. It is believed to have been the work of an incendiary.

Examiners Elect.—At the annual meeting of the State Board of Medical Examiners, held in Long Branch, July 6, Dr. John W. Bennett, Long Branch, was elected president; Dr. E. L. B. Godfrey, Camden, secretary, and Dr. Armin Uebelacker, Morristown, treasurer.

OHIO.

Personal.—Dr. E. Marion Foster has returned after a year abroad and has located in Cincinnati.

Warning.—Dr. Walter H. Snyder, Toledo, warns physicians against R. N. Rumnis, an individual of medium height, reddish hair, slender, fair-skinned, freckled, who offers premiums for subscriptions to *Collier's Weekly*; collects for a year's subscription, giving discount; leaves the premium offered, which half an hour later he borrows or steals.

Uniform Course Favored.—The State Board of Medical Examination and Registration met with representatives of several of the medical colleges, July 8, to arrange for a uniform curriculum throughout the state. Those who addressed the board were Drs. B. L. Milliken, Western Reserve Medical College, Cleveland; G. J. Jones, Homeopathic Medical College, Cleveland; Park L. Myers, Toledo Medical College and C. E. Walton, Cincinnati Medical College. All were in favor of a standard course of study. Drs. Ravogli, Wilson, Baxter and Towers of the board were appointed a committee to confer with the faculties of the medical colleges and report at the meeting in October.

PENNSYLVANIA.

Typhoid Alarms.—For the week ended July 25, 112 new cases of typhoid fever were reported in Pittsburg. The health officials forecast an epidemic and unanimously attribute the disease to the impure water supply of the city.

Crozer Hospital Opened.—On the anniversary of the birth of the donor, July 17, the J. Lewis Crozer Hospital, Chester, was formally opened. The construction and equipment of the hospital, done in accordance with the will of the benefactor, were supervised by Mrs. Crozer.

Impure Molasses Prosecutions.—The State Dairy and Food Department have served warrants on 25 dealers in Philadelphia on the charge of selling as the pure article adulterated molasses, which the law required to be marked "compound." This fight, Commissioner Warren is quoted as saying, is made against the "molasses trust," which, he says, has kept up this illegal traffic in defiance of the law.

Philadelphia.

Tenth Tetanus Death.—The tenth victim of tetanus from the Fourth of July toy pistol died in the Philadelphia Hospital last week.

Personal.—Dr. Henry W. Stelwagon has been made an honorary member of the National Dermatological Society of France.

Anti-Spitting Ordinance Enforced.—Enforcement of the anti-spitting ordinance has begun in earnest. A considerable number of men and boys have been arrested for spitting on the sidewalks. Some have been fined $1 and costs, the penalty the ordinance provides for each offense; several have been held under bail for further hearing. One refused to pay his fine and was held under $300 bail to keep the peace.

High Infant Mortality.—The infant mortality for the week ended July 25 was high, cholera infantum being ascribed as the cause of 82 deaths. There were 15 new cases of smallpox, as against 24 for the previous week. Director of Health Martin is quoted as saying: "Smallpox in this city is bottled up at least, and we have it under control." Physicians of the Department of Health continue to vaccinate bodies of workingmen and factory employes, and hospitals are requested to vaccinate all dispensary and accident cases not so protected.

Water Conduit Completed.—The blasting and digging of the largest water conduit in the world has just been completed. This is a part of the filtration system of Philadelphia under construction, and is to carry the water from the Torresdale filter plant to Lardner's Point pumping station. The work was begun 18 months ago. Much of the tunneling was through solid rock 100 feet under ground. The conduit is 14,000 feet long, and will have a capacity of 300,000,000 gallons daily. The portion of the filtration system completed, the Roxborough plants now yield 27,000,000 gallons daily, and the output will soon be increased to 5,000,000 gallons.

Management Unsatisfactory.—Dr. Martin, director of the Department of Health, was not satisfied with the management of the Municipal Hospital when he assumed the duties of his office. He has made several visits of inspection, and as a result improvements are reported. In published interviews Dr. Martin is reported to have charged "gross negligence" to the management. There are said to be many "leaks" for contagion, the wages of employes are in arrears, the plumbing is unsanitary, and an efficient disinfecting plant is needed. Radical changes in the personnel of the hospital staff are said to be contemplated, and it is not improbable that Dr. William Welch, who has been physician in charge for twenty-five years, will be relieved by another physician under the title of chief resident physician. Dr. Welch may be made consulting physician to the institution. Dr. Jay F. Schamberg is now assistant to Dr. Welch.

Infant Prophylaxis.—The Bureau of Health has begun, through the city district physicians, a census of all babies of the city under one year. The canvass is for the purpose of improving the hygienic care, especially the feeding of infants. The inspectors, on cards provided for the purpose, are to take a brief history of each infant and note its environment. A circular, printed in different languages, giving rules for the care of infants, is to be given to each mother. The inspectors are directed also to give simple instructions to mothers, and to urge vaccination in cases of infants not already vaccinated. It is the plan of the department to give public talks to mothers on the preparation of food and the management of infants, by physicians, who will volunteer to do so. The babies' directory is to be the basis of a scheme to lower the infant morbidity and mortality, especially during the hot months. This work is to co-operate with that of the modified milk plant which is being installed, and which is to furnish infants' food at cost.

GENERAL.

Leper Colony in Good Condition.—The annual inspection of the leper settlement on Molokai was completed July 20. Everything was reported in a satisfactory condition. Ten persons were found free from the disease and were released. Confirmation of the diagnosis of leprosy was announced concerning a number who had protested that the diagnosis was erroneous.

FOREIGN.

The Swedish Medical Association has lately been reorganized on practically the same plan as the American Medical Association.

Hospital at Port Arthur.—The Russian government has appropriated over a quarter of a million dollars to construct a large hospital at this point, with a sanatorium for patients with lung troubles.

Projected Asylum for Orphans of Physicians and Druggists.—Dr. E. Buday, of Budapest, has organized a committee which is soliciting subscriptions and arousing interest in the foundation of an asylum and school for this purpose in Hungary.

American Mosquitoes Plague London.—It is alleged that the notable increase in the number of mosquitoes about London is due to the importation by ships of American and South African

varieties, which bred prolifically on the new soil. It is said that England already had twenty-two varieties of mosquitoes.

The Gera Contract Practice Trouble.—The latest phase is that the sickness insurance societies refuse to pay their whilom medical officers for the last quarter of the year for which they served, claiming that they should be made to pay for the expenses caused the society by their resignations. The physicians have appealed to the courts.

The Approaching Sanitary Conference at Paris.—Italy took the initiative in summoning the international sanitary conference which will meet at Paris, October 10. No program has as yet been announced, but it is understood that the aim is to propose modifications of international sanitary measures based on the results of the latest researches.

Accident Insurance in Berlin.—In the further working out of the industrial accident insurance in Germany, the edict has recently been passed that the family is entitled to an indemnity when the victim of an accident contracts a fatal infectious disease in the hospital to which he has been transported. The regulations assume that the danger of infection is greater in a hospital, and that the subject is less resistant on account of the traumatism, so that the latter is indirectly responsible for his death.

The Knoll Prize in Bohemia.—The Philipp Knoll prize of 2,000 crowns was awarded this year for the first time, and not strictly in accordance with the ideas of the founder. It should be attributed to some one of the younger German-Bohemian scientists for the best work done in the last three years. Instead of that, it was divided among Professor Bayer and Dr. J. Langer, for work on congenital hernia and the lymph glands and bee poison, both dating from several years ago, and A. Fischel and O. Bail for recent research.

Institute of Legal Medicine at Paris.—A decree dated June 22, provides for the establishment of an institute for legal medicine and psychiatry for the training of experts for forensic cases. It will be in charge of the dean of the medical faculty, and lectures and practical instruction are to be given by various professors and hospital physicians. The *Progrès Médical* comments that if the institute is to depend on the city morgue for its material and is not to be equipped with up-to-date laboratories and spacious dissecting rooms, it will fall lamentably short of the purpose for which it is intended.

Sequel to the Nardenkoetter Charlatan Case.—The charlatan Nardenkötter, who escaped to England and forfeited his large bail rather than face his sentence of three years' imprisonment and a heavy fine, we learn has been handed over to the Berlin police by the English authorities. THE JOURNAL related some of the particulars of the sensational case at the time. The family bath tub in which the charlatan compounded his medicines has been satirized in many ways since. The gullibility of the public has seldom been better evidenced, although an ad that has been appearing in a German paper from the Munich charlatan, Weselmann, seems to count on still greater credulity. The latter advertises that he can diagnose all diseases, past, present, and those still in the germ, by examining the eyes. One of our exchanges comments that this method of treatment is not so much of a mockery of the science of the twentieth century as it is an arraignment of the laws which permit such a method to be publicly exploited for gain.

Penalties for Charlatans' Advertising in Germany.—The editor of the advertising portion of the Breslau *General-Anzeiger* was warned by the authorities in regard to the fraudulent character of the ads of a certain charlatan named Malisius, who claimed to cure all diseases. He continued to print the ads and has recently been condemned by the Breslau courts to a fine of 3050 marks, about $765. The court stated that the editor in publishing the advertisement was more culpable than the charlatan, as if the papers did not aid the quack he would not become so well known. Malisius himself was condemned on 22 counts of accomplished and 9 of attempted fraud, to a fine of 1500 marks, or $375, and eighteen months' imprisonment. A woman at Eberfeld has also been fined $40 because she advertised that she treated gynecologic affections, kidney and bladder troubles, gout, etc., "according to the latest scientific methods and researches," but was compelled to confess that she had not the slightest knowledge of recent scientific research.

Contract Practice in Germany.—The *Deutsche Med. Wochft.* announces that the medical officers of the sickness insurance societies at Munich unanimously resigned their positions July 1, as anticipated, on account of the increased demand on them to be imposed by the new legislation previously mentioned in these columns, and the refusal of the societies to increase their remuneration to correspond. A committee had been appointed by the "county" medical society to obtain the moral support of the local profession for this step on the part of the "*Kassen*" physicians, and the committee reported June 18 that more than 99 per cent. of the physicians in the province had signed the circular. The editorial commends "the organization of the Munich physicians, their unanimity and energy, as a shining example for us all." Later reports from Munich state that whereas, before the resignation of the medical officers the *Kassen* would not listen to their appeals, since then they have already made overtures for a consideration of the matter, which the profession hails as a material victory, and hopes for a speedy, peaceful settlement of the question.

British Degeneracy.—The question which we mentioned as exciting the English press and people, whether or not the British race is deteriorating physically, is exciting as much discussion there as did the "race suicide" matter in the United States. By way of continuing the matter under discussion and broadening its scope to include the mental status, the lay press quote Dr. Ernest W. White, professor of psychologic medicine at King's College, as having said in his presidential address to the Medical Psychological Association that facts point to an accumulation of the chronic insane and that the number of cases of melancholia had vastly increased, frequently resulting in chronic insanity. During the last few years Dr. White had been struck by the large number of cases of evolutionary mental breakdowns occurring in patients of the upper and middle classes from eighteen to twenty years of age. This was the result of the strain of education and the worries of life on brains unequal to the stress under which Londoners lived. Late marriages were more frequent than they were fifty years ago, and that did not conduce to healthy stock. Late hours, unnatural excitements and the greater stress of life all had their effect on the increase of insanity, and he feared that the race generally was less robust mentally, as well as physically, than formerly.

Cancer Research.—The German committee for cancer research announces the foundation of a "*Zeitschrift für Krebsforschung*" to be published by G. Fischer at Jena in connection with the *Klinisches Jahrbuch*, although as a separate periodical. The editors are to be Professor v. Hansemann and G. Meyer of Berlin. At the meeting of the committee, February 28, it was announced that collective statistics are being gathered in Spain under the leadership of Hans Leyden, nephew of von Leyden of Berlin. Great interest is being manifested also in Russia where a model Institute for Cancer Research has been erected at Moscow as previously mentioned in these columns. The English committee recently sent a delegate to Germany to study the arrangements there. "Prophylaxis of Cancer of the Stomach" was the main subject discussed, the importance of careful chewing being emphasized by Katz. Ewald, on the other hand, stated that in his experience cancer subjects had always lived temperately and chewed slowly and well. The contradiction between the greater prevalence of cancer in the large cities and in the well-to-do classes in opposition to its lesser frequency among the poor and in the country, where the food is coarse and not carefully chewed, was also brought out by some speakers. It can scarcely be explained by stronger teeth among country people. Von Leyden also corroborated the increasing frequency of cancer of the stomach in the well-to-do classes. He reiterated his belief in the parasitic nature of cancer, remarking, "We live on hope and work for the future."

Fee-Splitting in the French Courts.—A certain family physician at Joigny charged $100 for his share in conducting a case which required an operation for which the surgeon's charges were $400. The affair was carried into the courts and the physician's right to remuneration in connection with the operation was conceded, but the court decided that he must not charge in proportion to the expense of the high-priced consulting surgeon, but must be content with $30 instead of $100, thus fixing a standard rate for the attending physician in such cases. The *Progrès Médical* comments that a fixed charge is incompatible with the sliding scale generally adopted by the profession in accordance with the patient's means, from zero upwards. It cites as a laudable attempt to solve the question the suggestion by certain medical syndicates that the family physician should receive one-fourth as much as the surgeon. If this rate were once accepted and incorporated in the medical relations with the public, the latter would know beforehand and could count on the expense of an operation

and the after-care, and there would be nothing to conceal nor any suspicion of indelicacy on the part of the medical corps. The editor of the *Gaz. Méd. Belge* commenting on the same affair, remarks that the family physician can not always count on the good will of the family in respect to his emoluments in such cases. He suggests as remuneration for the responsibility of the diagnosis, preparation, etc., by the attending physician, that the specialist surgeon should charge a lump sum for himself and his aids, and that the attending physician should be considered and remunerated as one of his aids in the operation, which, of course, in most cases would amount to "division of fee."

LONDON LETTER.

Tsetse Flies and Trypanosomiasis.

The study of mosquitoes in connection with malaria and other tropical diseases undertaken by Prof. Ray Lankester and his assistant, Mr. F. V. Theobald, at the Natural History Museum, has given rise to an important monograph which is published by the trustees of the British Museum. It has been so useful to medical men working on these diseases that a similar study of tsetse flies is in the course of preparation. The tsetse fly of South Africa kills horses and cattle by introducing into their blood the *Trypanosoma brucci*. Dr. Castellani, a member of the Royal Society commission sent to Uganda to investigate sleeping sickness, has found in 70 per cent. of the cases a trypanosoma in the cerebrospinal fluid. It is suggested that the parasite may here also have been introduced by the tsetse fly. Professor Lankester has just received from Uganda a box of biting flies, which Mr. Austin, the expert dipterist of the museum, found to contain 10 tsetse flies of the species *Glossina palpalis*—a West African species known from the Gambia to the Congo. Dr. J. E. Dutton and Dr. J. L. Todd, who formed the trypanosoma expedition of the Liverpool School of Tropical Medicine, have just returned to England from Senegal. The expedition left Liverpool on August 21 last and proceeded to Bathurst in the Gambia. After working in the Gambia they went to Senegal. They found that trypanosomiasis occurs in both Europeans and natives, and is distributed from the sea to the upper Gambia. In Senegal the expedition received valuable assistance from the French authorities, who gave them every facility, including a large and well-equipped laboratory at St. Louis. They report that the anti-mosquito campaign at Bathurst has caused marked reduction in malarial fevers, both in Europeans and natives.

The Journal of the Royal Army Medical Corps.

A new journal, designed for the use of army surgeons, has just appeared under the editorship of Major R. H. Firth, professor of hygiene in the Army Medical School. The first number indicates that the journal will be one of high standing. It contains a minute and well-illustrated description of the hospital arrangements on board transports and a most interesting report of the medical relief expeditions to Martinique and St. Vincent in aid of the sufferers from the volcanic eruptions of May, 1902.

The Plague.

In Cape Colony, for the week ending June 20, the following cases were reported: Port Elizabeth, 2, 1 European female and 1 native male (found dead). At the Plague Hospital 1 native male died and 1 European male and 3 native males were discharged, leaving 8 cases under treatment. Plague-infected rats continue to be found in the town. At the plague hospital in East London 1 European female was discharged, leaving 4 under treatment. At King William's town 1 European female was discharged, leaving 11 cases under treatment. At Hong Kong for the week ending June 27 there were 54 cases (3 Europeans) and 35 deaths. In the market 5 ducks, a chicken and a quail were discovered, all of which had died from plague. The birds had apparently been infected from the basement dwellings in the market, and these dwellings will no longer be allowed to be used. In this connection it may be pointed out that Dr. W. J. Simpson, during his recent visit to the colony, showed that monkeys, pigs, calves, sheep, hens, geese, ducks, turkeys, and pigeons contracted the disease by feeding on infected material. These facts have a bearing on the mode of infection in man, and the prevalent view that he acquires plague mainly by inoculation. The fact that such a variety of animals can acquire the disease from their food suggests that he may also be so infected. It is the custom of the Chinese to eat half-cooked fowls and to use the uncooked entrails as a delicacy with their rice.

Sciatica and Rheumatoid Arthritis of Hip-Joint.

At the Polyclinic Dr. W. Bruce of Strathpeffer, a health resort for arthritic patients, almost went the length of maintaining that there is no such malady as sciatica in the ordinary meaning of the word (neuritis of the sciatic nerve), but that the cases so diagnosed are examples of arthritis of the hip-joint. It might be chronic rheumatic arthritis or acute or subacute gout. The pains in the thigh and leg he explained as "referred pains." He urged that there was never any anesthesia of the skin or reaction of degeneration. Neglect of examination of the hip was the cause of the mistake in diagnosis. Three supposed cases of sciatica were produced for demonstration. The points of differential diagnosis were gone through, and it was shown that in two out of the three cases the joint, and not the nerve, was affected. But in the third case no indications of joint disease could be elicited. All movements were borne without complaint, but pressure over the nerve caused flinching.

Correspondence.

Sacrificed to Eddyism.

Kansas City, Mo., July 14, 1903.

To the Editor:—I presume my indignation over and antagonism to the body known as Christian Scientists is but that of other members of the medical profession who have come in contact with them in case of serious illness and death, where their great assurance of power, though ignorance in reality, and criminality are demonstrated.

How we, an organized medical profession, and a civilized people, can or do permit them to continue to treat disease and surgical conditions in spite of common and frequent deaths due to their ignorance and neglect, is beyond comprehension! Yet I realize it is due no less to my tolerance than to that of thousands of others, both of the profession and the laity. We profess to have left behind us the Middle Ages with its superstitions, its atrocities and cruelties, but daily that period is being re-enacted in the homes of our neighbors, guided by the spirit of an autocratic despot, whose power for evil is quite that of her influence to instill professed happiness into the hearts of her deluded followers.

Within the past week I was called in to see a woman 73 years of age, a beautiful character, of bright mind, and extremely well preserved, and hopeful of living for years. For three days she had been ill and under the care of Christian Science healers and their nurse. It was evident I was called in by the family because her life was despaired of. An examination revealed a right, irreducible femoral hernia, frequent emesis, absolute constipation of three or four days' duration, localized pain on and without pressure. Gentle taxis, manipulation and hot applications proved of no avail at this time, though it can not be assumed in what such means might have resulted if resorted to at onset of descent of hernia. An operation was advised without delay, since the already serious symptoms were not only persisting but increasing, but in spite of advice and the horrible fecal vomit and the patient's agony, she was demonstrated over by these people calling themselves Christians, Scientists, Healers. In consequence, she died after an awful week—a victim to a pseudo-science—and in spite of the fact that an operation would have saved her. Through the ignorance and false faith of a sect fast attaching itself as a powerful factor in social and religious circles, this life was sacrificed, in fact, murdered.

Kansas City, like other cities and towns of the United States, has, during the past few years, had many deaths among Christian Scientists, and investigation has often proved, beyond a doubt, that death was not inevitable if medical service had been rendered. It would naturally seem that such instances would awaken the followers of Mrs. Eddy to a sense of their delusion, if not criminal responsibility. But, of course, to convince such devotees as come under the spell of a master, though degenerate, mind as is possessed by an Eddy or a Dowie, is not possible. The solution must, in all probability, come through popular education along lines of health and disease, and a persistent fight by the medical profession, for the passage of laws to protect society, especially the deluded adults of such a faith as in

question, and the innocent, ignorant children who often fall victims to lack of a humanity which is Christian, and knowledge and skill which are truly scientific.

I wish to urge that the profession at large report every such case that may come to their knowledge, and that at the next meeting of the American Medical Association, proper and decisive steps be taken, seeking state and, if possible, national legislation which may limit and punish directly those responsible for such deaths. It is a sad reflection on the owners and editors of our daily press that we can not, through them, have started a propaganda against such sects; and, too, most popular magazines are loath to take a decided stand against them. Hence, as in the past, the medical profession has waged a successful fight against germ disease, it remains for it to continue with more determination than ever the struggle against a pandemic of mental degeneracy. Otherwise, we will have lost power to control and cure many diseases and surgical conditions over which we now have power, and which is giving us a yearly decreasing death rate.

Scott P. Child.

Weakness and Dilatation of the Heart in Chronic Nutritional Disease.

New York, July 11, 1903.

To the Editor:—With interest I read the paper of Dr. G. W. McCaskey with the above title in The Journal, July 11, 1903. My interest will be readily understood if I may be permitted to quote from my own writings a few practical points in regard to the relation of myocarditis or feeble heart in general to atonia gastrica, and one remark about my carbonic acid gas baths to take the place of Nauheim baths.

In the year 1895 Dr. M. Einhorn pointed out to me the frequency of the occurrences of splashing sound (that is, atonia gastrica) in cases of heart disease. We examined together a number of cases and I published the result of this investigation in a paper ("What is the Significance of the Splashing Sound of the Stomach," *N. Y. Medical Journal*, June 15, 1895). Later on I followed this subject independently from Dr. Einhorn, and called attention to the importance of this symptom of atonia gastrica in its different forms in numerous papers. Among others I had observed how it seemed to correspond in many instances with tachycardia.

In one of these papers ("Gastroptosia the Cause of Symptoms Erroneously Attributed to Nephroptosia," *N. Y. Med. Journal*, June 21, 1903) I referred to a case reported by Dr. Groddeck of Baden Baden as follows:

> An elderly gentleman is suffering for several years from attacks of vertigo and unconsciousness. Almost daily, sometimes hourly, and even at shorter intervals, the alarming symptoms appear. The frequency of the pulse is 27-31 beats in the minute; only every second contraction of the heart causes pulsation. All the physicians who saw the case diagnosticated, quite correctly, myocarditic affection and treated him accordingly, but without success. The enormously distended belly of the patient had not been taken into consideration until Dr. Groddeck paid attention to it. The reduction of the size of the belly, although it did not cure the diseased myocardium, was followed by cessation of the attacks of vertigo and unconsciousness. The size, the weight of the belly, having been reduced the work of the heart was materially relieved, relieved to such an extent that even the imperfect contractions were sufficient to fill the brain with the necessary quantum of blood. it is sometimes of more importance in cases of heart disease to examine the abdomen than to distinguish the fine points of the auscultatory symptoms.

In every case of heart disease in which I find atonia gastrica I make it a point to relieve the relaxation of the abdominal viscera by means of plaster strapping, a method which I have frequently described. I have had invariably the satisfaction to see the beneficial effect on circulation and nutrition.

The absorption of large amounts of carbonic acid gas by the skin has a remarkably beneficial effect on the circulation, whether it is introduced into the rectum or dry gas baths are taken. The capillaries and arteries become dilated, the amount of blood in both, as well as the blood pressure in the arteries, is increased. The diastole of the heart becomes more effective. These are matters of significance, for the heart and its work in so far as the intensity of the peripheral arterial circulation is augmented, and the drawing of the blood from the veins facilitated. The diastolic filling is improved, and the heart muscle is given more time for relief and for renewed energy.

The question is now, why should we use the Nauheim baths to obtain this effect pure and simple of carbonic acid gas? The Nauheim baths are complicated, accidents are at least possible by the inhalation of the gas floating on the water. The dry gas baths, as they are given in Franzensbad, are perfectly harmless, no accidents, at least when the arrangements are made as I have made them, are possible, and the patient can enter without undressing. Every physician can improvise such a bath in his office.

A. Rose.

An Indian Bath.

Philipsburg, Mont., July 7, 1903.

To the Editor:—I noticed lately an article on the improvised Russian baths of the North American aborigine. In Wyoming, Idaho, Montana, Washington and British Columbia they are erected on the banks of streams, rivers and lakes, and in close proximity to a deep pool. Sometimes the work is extremely crude, just a few willow boughs slightly interlaced and barely large enough to hold an adult in a crouching position, the hole in the center, a shallow depression, and no attempt at comfort for the victim. Accompanying this is a photograph of the best constructed one I ever saw. It was made by Flatheads, or as they call themselves, "Selish." The length was 95 inches on the ground, and the height 81 inches in the center. The willows from each side are deftly twisted and braided together in the middle, the ends are tied with bright red flannel, of which a piece is continued over the top like a ridge pole; the hole in the center is 19 inches square, and nearly 13 inches in depth, and where the bather lies is spread with deep grass, called sometimes wild rye. This one was possibly used for more than one bather at a time.

E. F. Conyngham.

American Research and German Reviewers.

New York, July 21, 1903.

To the Editor:—Anent your editorial under above title I wish to state that the *Biochemisches Centralblatt* has since its inception endeavored to furnish abstracts, and in many instances auto-abstracts of all publications pertaining to the special field, and that the American collaborators have been instructed to prepare abstracts of every important article and to report the original works executed in American laboratories.

Heinrich Stern,
American Editor *Biochemisches Centralblatt*.

Queries and Minor Notes.

MEDICAL ETHICS.

Albert, W. Va., July 14, 1903.

To the Editor:—1. Dr. A. is in attendance on a case of appendicitis and he decides that an operation is necessary. The family ask that Dr. B. be called in consultation. Dr. B. agrees with

Dr. A. The family then ask that Dr. B. do the operation. This is not satisfactory to Dr. A., who had expected to do the operation himself. What course should each physician pursue?

2. Recently Dr. Z., a noted surgeon, was called to a neighboring state to operate on a physician. The operation was not successful and the physician died. Dr. Z. charged the brother of the physician for his services. Was this not positively unethical? A. P. B.

ANS.—Dr. B. should perform the operation, since the family request it. The patient and the family have a perfect right to decide on who shall perform the operation, in spite of the fact that it might not be pleasant for Dr. A. in this case.

2. The Principles of Medical Ethics of the American Medical Association, Chapter II, Article 2, Section 3, says:

> When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives.

One physician ought not expect another to render his services, pay traveling expenses, etc., without remuneration. The general principle is that if a physician can render services without very great inconvenience to himself, or too much expense, no charge should be made. If, however, as in this case, the physician must make a journey to a neighboring state to render these services, he should be compensated, but compensation under these circumstances should, of course, be the minimum which will pay him for his time and trouble.

RADIUM.

STANBERRY, MO., July 20, 1903.

To the Editor:—I notice an editorial on radium in the last issue of THE JOURNAL. Can you tell me where I can get a small quantity of the metal or its bromin salt? E. T. C.

ANS.—Radium is hardly yet a commercial product, and samples are obtained more by favor than otherwise. It is thus far more of a scientific curiosity than anything else.

State Boards of Registration.

Reciprocity in Oregon.—The Oregon medical practice act was amended by the last legislature so as to provide for reciprocity.

Suit to Oust California Examiners.—On the petition of Dr. David A. Hodghead, San Francisco, suit has been begun in the Superior Court to oust the members of the State Board of Medical Examiners. According to the newspapers, the complaint sets forth that the defendants hold their places by virtue of having been elected to represent on the board the Medical Society of California, the California State Homeopathic Medical Society and the Eclectic Medical Society of the State of California, and the petitioner holds that these are simply private organizations with no legal right to appoint anybody to public and salaried offices. The petitioner is dean of the College of Physicians and Surgeons of San Francisco, which had some trouble with the board last year.

Vermont Has Reciprocity.—The following amendment of Section 4633 of Chapter 190 of the Vermont statutes provides for reciprocity. The section as amended is as follows:

SECTION 4633. Each board of censors shall issue certificates to physicians and surgeons who personally present to such board a diploma from a medical college or university, and who also, by examination, satisfy said board of censors that they are qualified to practice the branches mentioned in said diploma; and to such physicians and surgeons, without examination, who shall personally appear and present a certified copy of certificate of registration or license, which has been issued to said applicant in another state of the Union, where the requirements for registration shall be deemed by said board to be equivalent to those of this state; provided, such state shall accord a like privilege to holders of certificates from a board of censors of this state.

The application fee is $5. The act is in effect since its passage.

Practice of Medicine Defined in North Carolina.—The following amendment defining the practice of medicine was passed by the general assembly of North Carolina and went into effect March 9, 1903:

SECTION 1. That Section 3122 of the code be amended by adding thereto the following words: For the purposes of this act the expression "practice of medicine or surgery" shall be construed to mean the management or treatment for fee or reward any case or disease, physical or mental, real or imaginary, with or without drugs, surgical operation, surgical or mechanical appliances, or by any other methods whatsoever.

Provided, that this act shall not apply to midwives nor to nurses.

Provided, further, that applicants not belonging to the regular school of medicine shall not be required to stand an examination except on the branches taught in their regular college, to-wit: the osteopaths shall be examined only on descriptive anatomy, general chemistry, histology, physiology, urinalysis and toxicology, hygiene, regional anatomy, pathology, neurology, surgery, applied anatomy, bacteriology, gynecology, obstetrics and physical diagnosis.

Provided, that this act shall not apply to any person who ministers to or cures the sick or suffering by prayer to Almighty God, without the use of any drug or material means.

Michigan Report.—Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the examination held at Lansing, June 9 to 12, as follows: Number of subjects examined in, 19; total number of questions, 190; percentage required to pass, 75; written examination; total number examined, 22; number passed, 18; number failed, 4.

Marriages.

JAMES F. DARNALL, M.D., to Mrs. Ora Waters, both of Obion, Tenn.

LEMUEL P. ADAMS, M.D., to Miss Elizabeth Leigh, both of Oakland, Cal.

DANIEL SIGLER, M.D., to Miss Mayme Bresler, both of Elwood, Ind., July 14.

JAMES H. FINCH, M.D., to Miss Helen M. Trevett, both of Champaign, Ill., June 10.

ROBIN W. C. FRANCIS, M.D., Cincinnati, to Miss May Edith Schellinger of Chicago, July 4.

WALTER BERNARD SCHWUCHOW, M.D., to Miss Jennie Isabel Gridley, both of Chicago, June 30.

Elmer Kline Avery, M.D., Chicago, to Miss May Francis Power of Escanaba, Mich., July 23.

Albert Mason Tyler, M.D., Oakdale, Mass., to Miss Alice Elizabeth Walker of West Boylston, Mass., July 15.

Eugene R. Hochstetter, M.D., Ridgedale, Tenn., to Miss Cleopatra Fleatsouth of Mission Ridge, Chattanooga, June 30.

Deaths.

Donald MacLean, M.D.

Dr. Donald MacLean, president of the American Medical Association in 1894, died from gastroenteritis, after an illness of two weeks, at his home in Detroit, Mich., July 24, aged 63.

He was born in Seymour, Ont., Dec. 4, 1839, of sturdy Scotch parentage. At the age of six he went to Edinburgh and attended school there for six years. He then returned to Canada and studied in Cobourg and Belleville schools; in 1855 he entered Queen's College, Kingston, where he remained two years. In 1858 he returned to Edinburgh for his medical studies, and

DONALD MACLEAN, M.D.

four years later received the degree of M.B., C.M., and licentiate of the Royal College of Surgeons, Edinburgh.

In January, 1863, he returned to America, and entered the Volunteer service as assistant surgeon, and remained for a year in the general hospitals at St. Louis, Harrisburg, Pa., Louisville, and New Albany, Ind.

In 1864 he accepted the chair of clinical surgery in the Royal College of Physicians and Surgeons, Kingston, and in the five years of his residence there acquired a large practice and gained a wide reputation as a teacher and writer. In 1869 he was obliged to resign on account of ill health, and spent three years in Edinburgh in rest and study.

He was made professor of surgery at the University of Michigan in 1872, and for seventeen years remained with that institution, resigning in 1889 on account of irreconcilable differences with the faculty, which opposed his plan of removing the clinical department from Ann Arbor to Detroit on account of the larger amount of clinical material in the latter city. He removed to Detroit and there built up a large practice.

In 1893 Queen's University conferred on him the honorary degree of LL.D., and a year later he was elected president of the American Medical Association. He was surgeon-in-chief for the Michigan Central and Grand Trunk railways and consulting surgeon at the Harper Hospital and Children's Free Hospital for twenty years.

He was a member of the Michigan State Medical Society, and its president in 1884; of the Detroit Medical and Library Association, and its president in 1887. He was also a member of the Royal College of Surgeons, London, and a Fellow of the Royal College of Physicians; and an honorary member of the state medical societies of Ohio and New York.

During the war with Spain he re-entered the service, and was commissioned major-surgeon, and assigned to duty at Old Point Comfort, Va.

He was a clear and forceful writer, and in addition to numerous contributions to the medical press, he was a collaborator with Mr. Symes in his great work on Surgery in 1884.

Dr. MacLean was a true Highlander, warm in his friendship and relentless in his hatred. He was a strong advocate of ethics and an uncompromising opponent of anything savoring of charlatanism, quackery or professional advertising. He was a stanch friend of the young practitioner, and his kindness to his patients and consideration for young practitioners won him hosts of friends.

He was at one time a bold and brilliant operator of the old school, but of late years his physical and mental condition had been such as to retire him almost completely from all kinds of labor.

Berthold Ernest Hadra, M.D. University of Berlin, Germany, 1866, surgeon in the Germany army in 1866; a resident of Texas since 1867; president of the Texas State Medical Association in 1901; one of the first regents of the University of Texas; and one of the founders of the medical department of the university at Galveston, died suddenly at his office in Dallas, July 12, from aneurism of the aorta, aged 58. At a meeting of the Dallas Medical and Surgical Society, July 14, committees on resolutions and floral tributes were appointed.

William J. Neilson, M.D. McGill University, Montreal, 1878, a member of the Manitoba Legislature; health officer of Winnipeg; one of the organizers of the Manitoba Medical College; gifted in his professional attainments, and highly esteemed in Winnipeg, died at the Winnipeg General Hospital, July 17, from lung disease of a year's standing, caused by a piece of gum, which lodged in the lung, for which an operation was performed without avail, aged 49.

Charles M. Galbraith, M.D. Barnes Medical College, St. Louis, Mo., 1897, assistant surgeon of the Fourth Illinois Infantry, U. S. V., in the Spanish-American War, and afterward captain and assistant surgeon of the Forty-Seventh U. S. Volunteer Infantry, died at his home in Carbondale, Ill., July 23, from tuberculosis contracted while in the Philippines, aged 31.

Herbert Mickle, M.D. Trinity Medical College, Toronto, 1881, of Buffalo, surgeon to the Emergency Hospital, demonstrator of anatomy in Niagara University and attending surgeon at the Sisters' Hospital, St. Francis Hospital, and the Church Home, died at Asheville, N. C., July 21, from tuberculosis, after an illness of two years, aged 42.

William Rittenhouse Hull, M.D. Pennsylvania Medical College, Philadelphia, 1858, died at his home in Williamsport, Pa., July 17, aged 66. He was an honorary member of his state and county medical societies. During the Civil War he was assistant surgeon of the 171st Pennsylvania Volunteer Infantry.

William H. Parish, M.D. Jefferson Medical College, Philadelphia, 1870, professor of anatomy in the Woman's Medical College of Pennsylvania, and chief medical director of St. Agnes' Hospital, Philadelphia, died from heart disease, after a long illness, July 19, at Bilsey Lodge in the Adirondacks, aged 58.

James N. Dickson, M.D. Berkshire Medical College, Pittsfield, Mass., 1866, died at the Mercy Hospital, Springfield, Mass., July 15, after an illness of two years, aged 60. He had practiced successively in Sheffield and Huntington, Mass., and for the last 20 years in Poquonock, Conn.

Samuel C. Hall, M.D. Eclectic Medical Institute, Cincinnati, 1869, St. Louis College of Physicians and Surgeons, 1892, an ex-member of the state legislature, a member of the American Medical Association, died at his home in Omaha, Ill., July 5, from pneumonia, aged 66.

Eugene Hodson, M.D. University of Maryland, Baltimore, 1856, died at Vienna, Md., July 10, from paralysis, aged 71. He was president of the Board of School Commissioners of

Dorchester County from 1872 to 1874, and in 1874 was elected to the house of delegates.

Simon C. Carver, M.D. Rush Medical College, Chicago, 1900, a member of the American Medical Association; for a time attending physician at the West Side Free Dispensary, Chicago, died from pneumonia, June 7, at his home in Chicago, after an illness of one week, aged 32.

Augustine Gattinger, M.D., one of the foremost botanists in the United States; surgeon in the Federal service during the Civil War; some-time state librarian of Tennessee, died at his home in Nashville, from pneumonia, July 18, aged 78.

J. B. Mitchell, M.D., surgeon of the Twelfth Tennessee Volunteer Infantry and the Fifth Kentucky Volunteer Cavalry during the Civil War, died at his home in Manhattan, Kan., July 2, from disease contracted during the war, aged 71.

Edward Vanderpoel Armstrong, M.D., passed assistant surgeon (lieutenant junior grade) U. S. Navy, retired, died at his home in Mount Vernon, N. Y., July 16, after a long illness from fever contracted in the tropics, aged 30.

William Gochrig, M.D. Philadelphia University of Medicine and Surgery, 1861, coroner of Lycoming County, Pa., surgeon of the Ninety-eighth Pennsylvania Infantry in the Civil War, died from acute gastritis, July 12, aged 71.

J. Ernestine Hills, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1893, physician at the Willard (N. Y.) State Hospital for the Insane, died suddenly at that institution from uremia, July 11, aged 41.

Charles A. Helvie, M.D. Rush Medical College, Chicago, 1894, died from the effects of chloroform self-administered, at his room in Los Angeles, Cal., July 10. He recently moved from Havelock, Neb., to California.

Harden E. Bozman, M.D. Dartmouth Medical College, Hanover, N. H., 1882, of New Alexandria, Ohio, died suddenly from apoplexy, July 6, while engaged in an obstetrical case, near Mingo, aged 45.

Isaac N. F. Beegle, M.D. Bellevue Hospital Medical College, 1870, a pioneer resident of Ocean Grove, N. J., died at his home in that place, from dropsy, July 20, after an illness of two years, aged 56.

Russell J. Collins, M.D. Berkshire Medical College, Pittsfield, Mass., 1850, a surgeon in the U. S. Army during the Civil War, died suddenly at his home in Georgetown, Colo., July 17, aged 75.

Francis Marion Perine, M.D. University of Buffalo, 1855, coroner of Livingston County, N. Y., for 21 years, died at his home in Dansville, July 12, after an illness of several months, aged 72.

H. H. McLellan, M.D. Medical College of Ohio, Cincinnati, 1880, formerly of St. Mary's, Kan., died at his home in Topeka, Kan., July 19, suddenly, from heart disease, aged about fifty.

F. A. Malick, M.D. Iowa College of Physicians and Surgeons, Des Moines, 1890, died at his home in Fullerton, Neb., July 17, from heart disease, after an illness of nearly a year, aged 36.

Gordon Herbert Race, M.D. Albany (N. Y.) Medical College, 1880, died at his home in Great Barrington, Mass., July 22, from heart disease, after a lingering illness, aged 50.

Andrew J. Clark, M.D. New York Homeopathic Medical College and Hospital, 1866, was fatally injured in a runaway accident at his home in Loveland, Colo., July 13, aged 74.

Alexander E. Jenner, M.D. Bellevue Hospital Medical College, New York, 1863, died at his home in Dayton, Ohio, July 12, after a long period of invalidism, aged 74.

William Preston Dowling, M.D., surgeon in the Confederate service during the Civil War, died at his home in Charleston, S. C., July 11, after a short illness, aged 70.

Alfred A. Gerish, M.D. New York Medical College, 1853, reputed to be the oldest practitioner in Indiana, died at his home in Lowell, Ind., July 17, aged 85.

James D. O'Keeffe, M.D. College of Physicians and Surgeons, Baltimore, 1873, of Tazewell, Va., died at Pulaski, Va., suddenly from heart disease, July 24.

Annie Lowe Geddes, M.D. New York Medical College and Hospital for Women, 1890, of Montclair, N. J., died from cancer, July 15, at Plainfield, N. J.

Richard R. Pettitt, M.D. University of Michigan, Ann Arbor, 1882, died at his home in Dayton, Ohio, July 9, from tuberculosis, after a long illness.

George Chappell Crawford, M.D. Long Island College Hospital, Brooklyn, 1894, died at his home in Brooklyn, July 13, after a brief illness, aged 34.

Henry A. Goodale, M.D., an old practitioner of Bay City and East Tawas, Mich., died at his home in the latter city, July 16, aged 81.

John E. Stanton, M.D. University of Pennsylvania, of Philadelphia, died at the Municipal Hospital in that city, July 11, from smallpox.

William Knight Adams, M.D. Hahnemann Medical College, Philadelphia, 1902, died at his home in Philadelphia, July 17, aged 23.

Thomas V. Loftus, M.D. University of Pennsylvania, Philadelphia, 1901, died at the Scranton Private Hospital, July 2, aged 26.

Olin G. Dyer, M.D. Castleton (Vt.) Medical College, 1844, died at his residence in Brandon, Vt., July 20, after a lingering illness.

Elias A. Howe, M.D., 1869, died at his home in Brancroft, Iowa, July 12, from Bright's disease, after a long illness.

Ebenezer E. Hyde, M.D. Castleton (Vt.) Medical College, died at his home in Belmont, N. Y., July 4, aged 84.

E. R. Dabney, M.D. New York University, 1845, died at the home of his son in Ringgold, Tenn., July 9, aged 78.

John Clarence Morgan, M.D. New York University, 1875, died recently at his home in Pompton Lakes, N. J.

Deaths Abroad.

Dr. Moritz Jacob Simon died of cerebral hemorrhage at his home at Gnesta, Sweden, June 27, aged 56 years, while making ready for a professional call. He had for many years been a member of the Board of the Association of the Provincial Physicians of Sweden, and at the same time its secretary. He was very much interested in public hygiene, an active worker for professional unity, and a faithful defender of the rights of the medical profession. Since 1898 he has been editor of *Eira*, a bi-monthly medical journal devoted largely to the interests of the country practitioners of Sweden and pro tempore also organ for Svenska Läkaresällskapet (the Swedish Medical Association).

Book Notices.

A TREATISE ON DISEASES OF THE ANUS, RECTUM AND PELVIC COLON. By James P. Tuttle, A.M., M.D., Professor of Rectal Surgery in the New York Polyclinic Medical School and Hospital. With 8 Colored Plates and 338 Illustrations in the Text. Cloth. Pp. 961. Price, $6.00. New York: D. Appleton & Co. 1902.

This volume of nearly 1,000 pages is the most comprehensive of the recent treatises that have appeared on this subject. The opening chapters are devoted to a consideration of the embryology, anatomy, physiology and malformations of the parts, to which nearly 100 pages are devoted. Methods of examination and diagnosis are then taken up, followed by a detailed description of the various pathologic conditions. A noticeable, at the same time excellent, feature of the work is the detail with which the author describes the treatment, whether operative, medicinal or hygienic. Nothing is left to be supposed, and no point which the author thinks may have a bearing on the case has been deemed too small to merit his attention. While this undoubtedly adds considerably to the size of the volume, it is a good fault, for success or failure often depends on some apparently unimportant detail of technic.

The general literature of the subject has been very well covered, and the methods of others receive proper consideration, but the author does not hesitate to say which particular method has given the best results in his own hands.

The illustrations are good and diagrammatic enough to give one a clear conception of the ideas intended to be conveyed. Most of them are new, yet occasionally one has perhaps been taken without due credit being given.

On the whole the book is a good one, and can be recommended to all who work in this line.

THE GEOGRAPHY OF DISEASE. By Frank G. Clemow, M.D. Edin., D.P.H. Camb., British Delegate to the Ottoman Board of Health. Cloth. Pp. 624. Price, $4.00. Cambridge: University Press. New York: The Macmillan Company. 1903.

This work, which is one of the Cambridge-Geographical Series, is an interesting and valuable little summary of the

geography of disease. It is based on reliable information from a vast number of sources, and the author has evidently gone over the literature thoroughly. So far as we are able to observe, his statements are generally correct. It is a curious thing to notice how many formerly serious and prevalent diseases have been of late years reduced in frequency and fatality in some civilized countries, while a few have evidently increased. The modern increase of pneumonia is not fully noticed, though from the date of the work we should think it would include this fact. The author's remarks that tetanus is not apparently common in the United States would seem to need some modification at the present time. The work is illustrated by maps showing the prevalence of certain diseases and their routes of transmission which are graphic and instructive. It is a valuable addition to what we might call semi-popular medical literature, which can not fail to also be of use to physicians.

Tuberculosis: Recast from Lectures Delivered at Rush Medical College, in Affiliation with the University of Chicago. By Norman Bridge, A.M., M.D., Emeritus Professor of Medicine in Rush Medical College. Cloth. Pp. 302. Price, $1.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This volume contains the substance of the lectures delivered by the author in Rush Medical College during the past three years, and is a summary of his wide experience in the treatment and control of tuberculous patients. The lecture form style is retained. We have seen few treatises on this disease that are more interestingly placed before the reader than this. Dr. Bridge's ideas in some respects have been criticised, especially those on lung gymnastics, etc., but we see nothing in this volume that would call for unfavorable criticism. It is an excellent little handbook of tubercular disorders, and complete in its description.

Miscellany.

Tuberculosis Fakers.

On the subject of our editorial, July 18, we quote the following from the *Medical News:*

The following from the *Herald* is worthy of preservation in medical literature as illustrating the methods of many similar institutions:

When the prosecution is ready to act in suppressing the many so-called "Koch" cure establishments purporting to be affiliated with Prof. Robert Koch, the distinguished German tuberculosis expert, but which he has expressly repudiated no less than thirty times in letters sent to representative men in America, a mass of testimony will be ready. In addition to the data already prepared for the counsel of the County Medical Society, which has been investigating these so-called "Koch" lung cure concerns for nearly two years, it was learned last week that a former nurse at the West Twenty-second street establishment, who has also had experience at several other branches, has volunteered to tell some astonishing particulars about the manner of conducting business in these "consumption parlors."

This woman is now employed at a hospital in this city. She first entered the employ of the so-called Koch Lung Cure Company in Philadelphia, where a sort of training school for nurses is maintained by the parent office. Then she went to the Rochester establishment. Here is what she said when asked about her experience there:

"I had charge of the business department there. I received the patients when they first came to the office; I placed the advertisements, prepared the tuberculin and was the general supervisor of the office. I kept the books and banked the money most of the time."

"What was the treatment that was adopted in that office during the time you were there in charge?" she was asked.

"We got the tuberculin from the Koch Lung Cure office, No. 150 Nassau street, in little bottles containing about an ounce. This was used with six ounces of albolene. The albolene was colored for the consumption cases and bronchitis, and the tuberculin that was used for asthma was plain white. We used alkanet root for coloring."

"How many patients were cured at that place?"

"None."

"How many ever gave testimonials as to being benefited or cured?"

"I think we got three who said they had been benefited, but never any that were cured."

This nurse was then asked about a letter which she said she had written by the direction of Wallace Cleveland Clark, M.D., the head of this particular so-called Koch Lung Cure Company, running as follows:

"We are interested in your case and want you to get well. We are glad to say that, through the generosity of a wealthy lady, whom we have cured, certain money has been placed at our disposal to assist deserving cases to take our treatment. Call soon, as we are making this same offer to others, and it will be a case of first come first served. Respectfully,

"K. L. C."

"What does 'K. L. C.' stand for?"

"The Koch Lung Cure."

"Was that the way Dr. Clark directed you to write the letter?"

"Yes."

"Do you know whether or not a generous lady, or any lady, was cured by the Koch lung cure and had deposited a sum of money for the purpose of benefiting other sufferers, as stated in this letter?"

"I can say positively that I know no wealthy lady was cured in Rochester and that there was never a dollar deposited for any such charitable purpose."

"What would you say basing your statement upon your experience with the company while you were in its service, and from your observation, is the main object of the company in its advertisements?"

"To get money, to get rich, and absolutely nothing else."

"From what you know of your own knowledge concerning the company's mode of treatment and sale of medicine and general advertisements, would you state whether or not there is any virtue in its treatment and if it does humanity good or relieves the sick and suffering from consumption?"

"I would not take it myself."

"What do you say generally, based on your experience?"

"I do not believe that it is any good."

Besides the testimony of this nurse, who has been in consultation during the last few days with Mr. Champe S. Andrews, the counsel for the New York County Medical Society, the method of the spurious "Koch" companies in obtaining testimonials has been investigated.

Here are extracts from a letter sent to a woman in Washington, D. C., signed W. C. Clark, the president of the concern:

"Dear Madam: You are probably aware of the fact that your testimonial has been inserted in the papers, and we realize that you are put to considerable trouble in answering letters and inquiries that come to you about your cure.

"Should any one desire to have you call and see them at their home and you can spare the time, we would be very much pleased to have you do it. Of course, a dollar would be a very small fee for such a visit and we would be very glad to pay it. . . .

"Kindly instruct us to answer them (the letters) for you and we will simply state that your case was cured, as stated in the testimonial. I believe that is all that is necessary. Hoping that you will take this in the spirit in which it is sent and will allow us to at least give you the amount that you would otherwise earn for the same amount of time given, I mean, twenty cents per letter and twenty cents for each inquiry. I remain, very sincerely yours, W. C. Clark."

This adroit scheme to obtain many alleged testimonials is said to have had an odd sequel, which may be brought out in the crusade of the County Medical Society against these impersonators of the German tuberculosis investigator.

Medical Organization.

Van Buren County (Iowa) Medical Society.

The physicians of Van Buren County met at Keosauqua, July 9, and effected preliminary organization of a county medical society.

Page County (Iowa) Medical Society.

Physicians of Page County met at Coin, June 25, and organized a county medical society, with the following officers: Dr. John A. Gillespie, Coin, president; Dr. Robert J. C. Dodds, Blanchard, vice-president, and Dr. Charles F. Perkins, Shenandoah, secretary and treasurer.

St. Landry Parish (La.) Medical Society.

Physicians of St. Landry parish met at Opelousas, July 10, and organized a parish medical society with the following officers: Dr. Benjamin A. Littell, Opelousas, president; Dr. Ladis Lazarro, Washington, vice-president; Dr. William R. Lastrapes, Opelousas, secretary, and Dr. William R. Boudreau, Washington, treasurer.

Grand Forks County (N. D.) Medical Society.

Thirty physicians of Grand Forks County met at Grand Forks, July 8, and organized a county society with the following offices: Dr. John D. Taylor, Grand Forks, president; Dr. Herbert W. Matthews, Emerado, vice-president; Dr. Henry H. Healy, Grand Forks, secretary, and Dr. Robert D. Campbell, Grand Forks, treasurer.

Lafayette Parish (La.) Medical Society.

At a meeting for organization held at Lafayette, July 11, this society was formed; a constitution and by-laws on the lines suggested by the state and National associations adopted, and the following officers elected: Dr. Jean P. Francez, Carencro, president; Dr. John D. Trahan, Lafayette, vice-president, and Dr. Felix E. Girard, Lafayette, secretary and treasurer.

Jefferson County (Texas) Medical Society.

Pursuant to call, the physicians of Jefferson County met at Beaumont, July 19, and organized a county medical society, and adopted a constitution and by-laws in conformity with those of the state and National associations. Dr. William W. Cunningham was elected president; Dr. Louis Goldstein, vice-president; Dr. Guy H. Reed, secretary and treasurer, and Dr. Henry A. Barr, delegate to the state medical assocation.

New Hanover County (N. C.) Medical Society.

On July 6 Dr. Frank H. Russell, Wilmington, councilor for the Third District, met with the physicians of the county at Wilmington and completed the organization of the society. Dr. Thomas S. Burbank, Wilmington, was elected president; Dr. John T. Schonwald, Wilmington, vice-president, and Dr. E. J. Wood, secretary. Drs. William D. McMillan and Andrew H. Harriss, Wilmington, and S. E. Koonce, Polloksville, were elected censors.

Russell Springs (Ky.) Medical Society.

The president, Dr. James G. Carpenter, Stanford, councilor for the Seventh District, announces that this society will meet August 13 and 14; that at this time the Adair and Russell County Medical societies will be organized, and closes with the following invitation: "Let everybody come and bring his rifle and fishing tackle. Rattlesnakes are sufficiently numerous in this section of the country for each member to supply himself with the necessary antidotes before he leaves home."

Hunt County (Texas) Medical Society.

Dr. Charles E. Cantrell, Greenville, councilor for the North Texas District, met the physicians of the county at Greenville, July 7, and assisted in the organization of the county medical society under the jurisdiction of the state and National associations. Dr. Walter C. Welch, Caddo Mills, was elected president; Dr. Thomas J. Milner, Greenville, vice-president, and Dr. Milus L. Moody, Greenville, secretary-treasurer. Drs. Thomas E. Spaulding, Greenville, W. B. DeJernett, Commerce, and Garnett, were elected censors.

Monona County (Iowa) Medical Society.

Physicians of Monona County met at Onawa, July 1, and with the aid of Dr. Edward Hornibrook, Cherokee, councilor for the Eleventh District, organized a county medical society on the lines suggested by the state and National organizations. Dr. John W. Huff, Onawa, was elected president; Dr. Rueben Harmon, Onawa, vice-president; Dr. E. E. Fisher, Rodney, secretary, and Dr. Archillous A. West, Moorhead, treasurer. Drs. A. J. Moore, Onawa, W. W. Gingles, Castana, and John D. Kerlin, Whiting, were elected censors.

Dallas County (Texas) Medical Society.

Pursuant to call of Dr. Charles E. Cantrell, Greenville, councilor for the North Texas District, physicians of Dallas County met at Dallas, July 11, organized a county medical society, adopted the constitution and by-laws prepared by the American Medical Association, and elected the following officers: Dr. Vene P. Armstrong, Dallas, president; Dr. Alva W. Carnes, Hutchins, vice-president; Dr. Elbert Dunlap, Dallas, secretary; Dr. John C. Armstrong, Garland, treasurer, and Drs. W. W. Samuell, Frank J. Hall, and Jesse B. Titterington, Dallas, censors.

Societies.

Medical Society of the Missouri Valley.—The annual meeting will be held in Omaha, September 17.

Jasper County (Iowa) Medical Society.—At the annual meeting in Newton, July 16, Dr. Louis S. C. Turner, Colfax, was elected president; Dr. F. L. Smith, vice-president; and Dr. Harry P. Engle, Newton, secretary and treasurer.

Southwestern Minnesota District Medical Society.—At the thirtieth semi-annual meeting held in Windom, July 16, Jackson County was added to the jurisdiction of the society, which formerly included five counties—Rock, Pipestone, Murray, Nobles and Cottonwood.

Stephenson County (Ill.) Medical Society.—The following officers were elected at the annual meeting held in Freeport, July 9: Dr. Jeremia H. Stealy, Freeport, president; Dr. Daniel B. Bobb, Dakota, vice-president; and Dr. Robert J. Burns, Freeport, secretary and treasurer.

Henry County (Iowa) Medical Society.—At the annual meeting held in Mount Pleasant, July 14, Dr. James M. Evans, Salem, was elected president; Dr. Charles W. Gardner, Winfield, vice-president; and Dr. William S. Lessenger, Mount Pleasant, secretary and treasurer.

Denton County Medical Association.—At the annual meeting, July 7, held in Denton, the following officers were elected: President, Dr. Franklin U. Painter, Pilot Point; vice-presidents, Drs. Milton C. McBride, Denton; George G. Agerton, Argyle, and Curvier Lipscomb, Denton; secretary, Dr. Melvin L. Martin, Denton, and treasurer, Dr. James B. Honeycutt, Denton.

Association of Assistant Physicians in the Ohio State Hospitals.—At a meeting called at Columbus, July 16, this association was organized with a charter membership of 25. The following officers were elected: President, Dr. George T. Hardin, Jr., Columbus; vice-president, Dr. James F. Kelly, Cleveland; secretary, Dr. Isabel A. Bradley, Columbus, and treasurer, Dr. Nelson H. Young, Toledo.

Lehigh Valley Medical Association.—At the twenty-third annual meeting held in Stroudsburg, Pa., July 16, the following officers were elected: President, Dr. Frederic Corss, Kingston; vice-presidents, Drs. John T. Howell, Wilkesbarre, E. H. Deckinshied, Nathaniel C. Miller, Stroudsburg, and C. B. Smith; Dr. Charles McIntire, Easton, secretary; Dr. W. B. Walker, assistant secretary, and Dr. Abraham Stout, Bethlehem, treasurer. The next session will be held in Allentown in January, 1904.

Tri-State Medical Association of Western Maryland, West Virginia and Western Pennsylvania.—This society met at Cumberland, Md., July 16, and elected the following officers: President, Dr. Martin F. Wright, Burlington, W. Va.; vice-presidents, Drs. James O. Bullock, Lonaconing, Md.; A. B. White, Connellsville, Pa., and Edwin K. Wilson, Romney, W. Va.; recording secretary, Dr. Percival Lantz, Alaska, W. Va.; corresponding secretary, Dr. Frederick W. Fochtman, Cumberland, Md., and treasurer, Dr. Henry W. Hodgson, Cumberland, Md.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Thirteenth Annual Meeting, held at New Orleans, May 4, 1903.

(*Continued from page 275.*)

Report of Committee on Revision of Constitution as to the Standard of Admission.

DR. WM. H. WATHEN, Louisville, Ky., presented the following as a minority report:

MINORITY REPORT.

MINIMUM REQUIREMENTS FOR ADMISSION TO A MEDICAL COLLEGE.

In adopting a standard of minimum educational requirements for admission to the freshman year of a medical college, to govern the members of an Association representing the entire country, the college being a department of a university, or in affiliation with a university, or with no university connection, it is necessary that concessions be made, so as to agree on what is best in the interest of the greatest number of reputable medical colleges, and in obtaining the best results in the prevention and cure of disease. A standard too high may be as harmful as a standard too low, by excluding from the medical profession men of the best minds, who are deprived of the cultural training in a large and expensive university; hence, to adopt a universal requirement of a baccalaureate degree from a recognized college or university for admission to a professional school would alike be at this time an injustice and injury to the profession and the people. Therefore, we must philosophically consider the conditions that underlie and control the educational system in this country leading up to the admission to the university and professional school, for these conditions differ radically from what pertains in other civilized countries. In England, Germany, France and other European countries, the free public school system does not offer opportunities for an education higher than that obtained in the six or eight years of our best primary and intermediate schools, and the few who are permitted to pursue their studies in the secondary or so-called high schools, are confined to the wealthy and aristocratic class, or to the well-to-do people of the middle class who are able to pay fees. Our system offers to any one a continuous course averaging from ten to twelve years from entering the primary school to the college or university, while in Germany the peoples' schools are intended primarily for the low and middle classes, and have little connection with the high schools which prepare students for the university. In Italy the connection between the elementary and secondary school is apparently closer than in Germany, but practically the reverse is true, for 90 per cent. of the children never pass beyond the third year's course of the primary schools.

In France, because of the fees charged, and the difference in organization and purpose of the two classes of schools, the graduates from the primary schools (écoles primaires élémentaires) seldom enter the high schools (lysées and colleges). The same is practically true in Switzerland, and apparently the same reasons keep down the number of secondary schools. In Zurich, where the conditions of advancement are exceptionally good, of 1872 graduates of the primary school in 1899, only 482 entered the secondary school, and probably but few of these were able to complete the course. The board schools of England, which are for, and attended by, the masses, are entirely different in spirit and in purpose from the public and grammar schools which prepare students for the university. Stimulated doubtless by the privileges and results of our public system of education, England has organized higher grade elementary schools, which may have a course of four or five years longer than the lower schools; and Germany has similarly sought to supplement the work of the primary schools by establishing real schools and higher burgher schools, but in none of these schools is either Latin or Greek taught, and the courses do not lead up to the university; the same is true in results in the higher primary schools (écoles primaires supéreures) of France.

While our system in its inception may have been in a degree fashioned after foreign models, and the establishment of our system of elementary education influenced by the description of European schools, by Mann, Stowe and Barnard, the difference between the American and European schools in organization and methods is now so great that in many features we can not and should not resemble those schools. We may in the future, as we have in the past, gain much from foreign schools, and foreign literatures, but our highest ideals must result from indigenous influences, truly American, and not ideals or practices found elsewhere.

The success claimed in the fixed courses in the German high schools in large cities to show the unwisdom of our elective courses is not sustained by facts, for in each of those cities there are several high schools whose curricula differ as widely as the various courses in a high school with us. It must also be remembered that the lycée of France and the gymnasium of Germany are intended for the few who may obtain a liberal education, while our schools supply the needs of all.

It will thus be conceded that in European countries but few pupils can be properly educated for admission to professional schools except through colleges and universities, while in the United States they can be well prepared in our free public schools. But as the curricula in our primary, intermediate and secondary schools differ, not only in various states, but even in the different schools of each state, both in time and in amount and character of work required, we should, in accepting a high school diploma as a minimum qualification for admission, correctly understand and determine the time-requirement, and in a general sense the amount and character of education given—being liberal in the allowance of electives. In view of the fact that most of our states and cities in which the public school system is encouraged and fostered require attendance upon twelve years of not less than forty weeks each from the beginning of the primary to the completion of the secondary course, the Association should finally expressly provide that the diploma of no high school obtained in less time shall be accepted as a minimum requirement for admission to a medical school. The high school can never offer fixed, or even elective courses to especially prepare the pupils for the several professional schools, nor can this be completely done in our universities, unless those studies properly belonging to the academic and scientific department be subordinated to studies that have usually been included in the professional schools, and should be retained, if we are to have any unit of measure for the baccalaureate and professional degrees.

In this process of rapid evolution in education to meet modern demands, the regulator necessary for perfect results has not worked with entire precision, having permitted the destruction or injury of many cherished precedents that time must restore, and made innovations that time must destroy. This applies especially to our well-known universities in their desire to shorten the period of university residence, by the substitution of professional work for the time-honored purely academic work; the work of the senior year, and in the University of Chicago in the two years of the senior college, being mainly professional, the pupil receiving the baccalaureate degree and advancing the sophomore or junior year of the four years' professional school, thus obtaining the baccalaureate and professional degree within six or seven years, each degree indicating that it had been obtained after attendance on four years of academic or professional work. It is also possible for a pupil whose qualifications will admit him to the junior year of the university to obtain in five, and in the University of Chicago in four years, both the baccalaureate and professional degree. This is no captious criticism, but a desire to direct attention to a heterogeneous condition, inconsistent with all classical conceptions of a university proper, and which the philosophic deductions of our most distinguished teachers and scholars will eliminate. It is especially the province of the university to teach the science and art of education, its history and methods, and create a demand for more thorough professional training: It should produce a succession of scholars in philosophy and literature, but it is not required to supply practitioners in the professions; for if the university observes its purest ideals, the professions will take care of themselves.

The degree of perfection in the work in primary and secondary schools, academies and colleges, may be measured by the perfection of the classical work done in the university, for as the sun gilds the mountain tops before its light floods the plains, so must educational progress spread from the summits, for the secondary schools receive their inspiration from the classical university, and will be what the university makes them. With the proper stimulus and encouragement of the university, the secondary schools may finally complete the work of the freshman and sophomore years, thereby reducing the university residence to six years in obtaining the baccalaureate and professional degree—thus eliminating the combined academic-professional course, and giving a unit of measure to both degrees.

In our effort to adopt the best method of education preparatory to the study of the professions, we often confound culture with instruction, and wisdom with knowledge, forgetting that culture is to quicken, strengthen and enrich the mind, while instruction furnishes the mind with knowledge, which may be

abundant, but of little value unless utilized by wisdom to obtain the most perfect results which may redound to the greatest interest of humanity. Wisdom and knowledge are not identical, but related, and the latter can not be possessed without a degree of the former. Knowledge comes from without; wisdom lies within, but by cultivation may become comprehensive and powerful. Much knowledge may be worthless unless directed by the guiding-star of wisdom. Knowledge is the material out of which we construct the beautiful palace, but wisdom is the architect who combines this material in harmonious relation, resulting in architectural perfection. Then while in our preparatory education leading up to the study of the professions, let us educate the mind to think rightly and wisely. We should encourage the study of the classics—English, Mathematics and the Sciences—but we should teach the mind how to digest, assimilate and appropriate the accumulated facts; otherwise there may be much knowledge with little wisdom, and no useful results. Teach the student the various channels and mechanisms by which knowledge may be obtained, and the mental processes by which it may be directed and utilized to attain the greatest perfection and usefulness. Teach him philosophy—embracing psycology, logic and ethics—and in a general sense the history of phil- and usefulness. Teach him philosophy—embracing psychology, of Socrates, Plato and Aristotle, the Pagan philosophy of Rome, and finally through the various ages, to Abelard, Descartes, Kant and others equally worthy.

The study of too much mathematics, as also some of the collateral sciences, should be discouraged, and the time may better be consumed in a careful study of English, and Greek and Roman history, and in the life and growth of language, especially of the philology of the languages that may be traced to an Aryan or Indo-European origin.

Of all languages except our native tongue, the study of Latin is of greatest value, and excluding the commercialism of German and French, Greek should be next in order, for even an imperfect knowledge of these two languages will enable the student to easily understand the etymology of the many compound technical terms in the study of medicine, which a knowledge of no other language will do. German can never be of much value in the study of the rich scientific literature of that language, unless it can be read with ease and correctly translated, and this can not be done by the American student of four years' study of five hours a week in our high schools. Again, in the near future, all that France or Germany may discover or develop, if of real value, will be promptly given to us in a translation, by scholars educated in German or French, English and the sciences; and even to-day we find many such translations in libraries throughout the country. Far be it from me to discourage the value of German and French, and the great richness of their literatures, but to be of value to the student in medicine, the languages must be read with ease, otherwise the meaning may not be correctly understood, for the understanding of the text must be measured by the translation. The average student in German who graduates from our high schools may read German with comparative ease in the text-books in prose and poetry, but he can not read with ease books on technical and scientific subjects, and to do so at all, he must constantly refer to his lexicon and make slow progress. This is true of our high schools in Louisville, with teachers acknowledged to be equal to any in the country, the course being four years of ten months each, five hours a week. This is also true in the state of New York, as will be seen in the following extract from a recent letter from Prof. Charles R. Skinner, state superintendent of department of public instruction: "Graduates from our high schools do not, as a rule, read with ease the German and French languages."

My information from extensive correspondence indicates similar results in the various states. Of course pupils of German parentage, or of special excellence may read and write the German language with ease. It must also be remembered that German is a required study in but few of our high schools, and in many of them is taught but two years; therefore, in adopting a minimum requirement for admission to medical college, neither German or French should be demanded, but should be encouraged as electives. Then let us adopt but few fixed subjects in our examinations for admission to a medical college, but many electives from which selection may be made, requiring one-third, or about seven out of twenty-one. In accepting a baccalaureate degree for admission, we are forced to acknowledge that it is meaningless, has no significance, and indicates nothing if conferred by the majority of our so-called academies, colleges and universities, and who is to sit in judgment to separate the chaff from the wheat, the bad from the good, the sinner from the saint? as all claim equal virtue. Then if this be true in accepting a baccalaureate degree for admission, the evil will be far greater in giving advanced standing or time-credits for such degree. So let us urge on this Association to give no time-credits for work done, except in a recognized medical college, and to insist on a discontinuance of the combined academic and professional courses. If this can not be accomplished now, it will be in the very near future, for the evolution is rapid in that direction, as indicated in the subjoined letters from the officers of the academic and arts department, and the medical department of Harvard, Johns Hopkins, Yale, Cornell, Columbia, etc. None of these universities gives time-credits for a baccalaureate degree, and Harvard and Johns Hopkins have no combined academic and professional courses, and I am sure neither Columbia, Yale or Cornell will have after a few years, for they encourage their students to attend four years of purely medical college work. The combined course was the child of necessity, to meet the demands for a shorter university residence, the medical profession refusing to recede from the requirement of attendance on four years purely medical work. As it is hardly possible to increase the university residence, the academic and arts course must be finally reduced to three, and possibly to two years, which may be done without lowering the standard by requiring applicants for admission to have done the work that has previously been included in the freshman, or both freshman and sophomore years. The secondary schools will then teach more months and more hours, with a better system and more condensed work, eliminating all that a broader experience proves to be unnecessary. The student may then graduate in medicine when he is twenty-three, twenty-four or twenty-five years old; ten to twelve years in the primary, intermediate and secondary department, two to three years in the college, and four years in medicine.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Prophylaxis and Treatment of Baldness.

Dr. Albert Bernheim, in an article in *Amer. Med.*, states that the greatest hindrances in stopping the falling out of the hair are the indifference and impatience of the patient and the physician. In his opinion brain work is not a causative factor of baldness, as is the exclusion of light and air from the hair. He outlines his treatment as follows: 1. Time. 2. Patience. 3. Tar soap containing 40 per cent. of birchwood tar or beechwood tar to 60 per cent. of the soap mixture.

The scalp should be shampooed with this soap every day for at least eight weeks. The shampooing must occupy not less than ten minutes. The soap should then be washed off with warm water, the hair and scalp well dried by patting with tissue paper or paper napkin; it must not be rubbed dry.

4. The following should then be rubbed on the scalp:

℞. Sol. hydrarg. chloridi corros. (1 to 300) |
Glycerini |
Spts. cologne, āā.....ʒiiiss 100|

M. Ft. solutio. Sig.: Apply locally with soft woolen tissue and rub for five minutes.

After this application, rub the scalp dry with the following solution:

℞. Beta naphthol .....gr. xv 1|
Alcoholis (absolute) .....ʒvii 210|

M. Sig: Apply locally.

This should be followed by applying freely the following:

℞. Acidi salicylici .....ʒss 2|
Tinct. benzoin .....m. xlv 3|
Olei (neatsfoot) .....ʒiiiss 100|

M. Sig.: Rub the scalp thoroughly for five minutes.

The soap solution is employed to remove all dust which may adhere to the scalp. The sublimate stimulates the growth of

the hair. The naphthol mixture dries the scalp and removes the fatty substances and aids in absorption of the oil. The purified neatsfoot oil is supposed to be better absorbed than the vegetable oils. The author states that lanolin may be substituted if desired. Good results have been obtained in the treatment of alopecia areata in a similar manner.

In alopecia due to syphilis the following combination has been advised by Besnil:

℞. Olei cadini .....m. xlv 3
Sulphuris precip. .....gr. xv 1
Resorcin .....gr. ivss 30
Acidi salicylici .....gr. iiss 15
Adipis benzoinati .....ʒi 30
M. Ft. unguentum. Sig.: Apply locally.

Lyon, in *Progrès Méd.*, recommends the following in the treatment of baldness:

℞. Quininæ sulph. .....gr. xv 1
Olei theobrom.
Olei ricini, āā .....ʒiv 15
M. Ft. unguentum. Sig.: Apply locally; or:

℞. Tinct. cantharidis .....ʒiiss 10
Acidi acetici .....gtt. xv-xxx 1.-2
Pilocarpinæ hydrochlor. .....gr. viiss 50
Glycerini .....ʒvi 24
Eau de Cologne .....ʒvii 210
M. Ft. lotio. Sig.: Apply locally with thorough friction.

Diabetic Coma.

According to an abstract in *Medicine*, Arthur R. Elliott states that prophylaxis is of the first importance. According to the author there are signs, preceding by several days the development of coma, which may be developed by examination of the urine. Acetone is the first to appear, later diacetic and oxybutyric acids. These may be detected by adding a solution of ferric chlorid which produces a wine-red color. If this reaction is present, the patient should avoid cold and fatigue. Elimination should be promoted, and the patient instructed to drink water freely. Colonic flushings and laxatives should be given. Previous to development of coma, sodium bicarbonate should be given in large doses. If coma occurs the patient should be put to bed and stimulants administered and the bowels evacuated. Alkalies should then be administered, using sodium bicarbonate hypodermically with the normal saline solution, also given per rectum.

In very severe cases a solution made up as follows should be injected into the venous circuit:

℞. Sodii bicarb. .....ʒiiss 10
Sodii chloridi .....ʒiss 6
Aq. destil. .....Oii 900
M. Sig.: To be injected into the venous circuit or beneath the skin.

Lecithin in Tuberculosis.

Bernheim, according to *Merck's Archives*, recommends lecithin administered hypodermically and combined with guaiacol as follows:

℞. Lecithin
Guaiacol, āā .....gr. xv 1
Olei olivæ (washed in alcohol and sterilized) .....ʒiiss 10
M. Sig.: Inject 15 to 30 minims (1.-2.) every other day.

Ichthyol in Chronic Bronchitis.

De Brun, according to an abstract in *Ther. Gazette*, recommends the use of ichthyol internally in the treatmtent of chronic bronchitis. It is given in daily doses of fifteen grains, made up in pill form. He reports excellent results in diminishing the cough and giving the patient rest. The dyspnea rapidly disappears and the râles over the chest decrease in number. This preparation may be given in the liquid form combined as follows:

℞. Ichthyol .....gr. xxx 2
Glycerini
Syr. aurantii, āā .....ʒss 15
Aquæ q. s. ad .....ʒiii 90
M. Sig.: One half to one teaspoonful several times a day in water.

Chlorosis with Phlebitis.

Carriére, according to the *N. Y. and Phila. Med Jour.*, recommends, in the treatment of phlebitis complicating chlorosis, that the patient be put to bed and the affected limb immobilized, after wrapping it in cotton, for thirty days. Locally, along the course of the inflamed vein, the following is applied:

℞. Olei hyoscyami
Spts. chloroformi, āā .....ʒiiss 10
M. Sig.: Apply locally.

In the treatment of the chlorotic condition a rich diet is prescribed and the following combination given internally:

℞. Ferri oxylatis .....gr. ii 12
Magnes. carb.
Pulv. gentianæ, āā .....gr. iv 25
Pulv. rhei .....gr. iii 20
M. Ft. capsulæ No. ii. Sig.: Two such capsules at one dose and repeated twice daily before meals.

In order to hasten the absorption of the iron as it is absorbed in the form of the chlorid, the following is recommended:

℞. Acidi hydrochlor. dil. .....m. xlv 3
Aq. destil. q. s. ad .....ʒx 300
M. Sig.: One tablespoonful after each meal.

Salicylic Acid Externally in Rheumatism.

Timireff, in *Rev. de Ther.*, recommends the employment of salicylic acid by external application in the treatment of articular rheumatism. It may be combined as follows:

℞. Spts. terebinthinæ .....ʒss 2
Acidi salicylici .....ʒiiss 10
Adipis .....ʒiii 90
M. Ft. unguentum. Sig.: To be applied locally to the inflamed joint; or:

℞. Acidi salicylici
Olei terebinthinæ
Lanolini, āā .....ʒiiss 10
Adipis .....ʒiii 90
M. Sig.: Apply locally three or four times daily.

By this mode of medication, according to the author, rapid absorption takes place, any disturbance of the stomach is avoided and the pain is relieved. The oil of wintergreen may be substituted for the salicylic acid if preferred.

Disturbances in Gastric Secretion.

The following treatment is recommended by Rankin in *British Med. Jour.* where there is a deficient secretion of gastric juices:

℞. Acidi hydrochlor. dil. .....m. xv 1
Acidi carbolici .....gr. ii 12
Sol. strychninæ (1 per cent.) .....m. v 30
Tinct. zingiberis .....m. xv 1
Glycerini .....ʒss 2
M. Sig.: To be taken at one dose and repeated an hour after each meal, well diluted in water.

If the patient is anemic the following pill should be prescribed after each meal instead of the foregoing solution:

℞. Quin. sulph. .....gr. i 06
Ferri sulph. .....gr. ii 12
Acidi carbol. .....gr. iss 09
Strych. sulph. .....gr. 1/60 001
M. Ft. pillula No. i. Sig.: One such pill after each meal.

When the patient complains of hyperacidity the following is of value:

℞. Bismuthi carb. .....gr. xxx 2
Spts. ammon. arom. .....ʒss 2
Acidi carbol. .....gr. ii 12
Sol. strychninæ (1 per cent.) .....m. v 30
M. Ft. solutio. Sig.: Shake the mixture and take the entire amount at one dose and repeat it two hours after each meal.

In the nervous form of gastric disturbance the following:

℞. Zinci valerianatis .....gr. iii 20
Acidi carbol. .....gr. ii 12
Acidi arsenosi .....gr. 1/40 0015
Ext. cannabis ind. .....gr. 1/4 015
M. Ft. cap. No. i. Sig.: One capsule after each meal.

Headache.

Buchanan, in *Med. Summary*, recommends the treatment of the cause. If it is dependent on gastric acidity, the stomach should be emptied and the following given:

℞. Spts. ammon. arom. .....3ii 8|
Sodii bromidi .....3ii 8|
Aquæ q. s. ad .....℥iii 90|
M. Sig.: One tablespoonful every two or three hours.

If the headache is due to acute cerebral congestion, the feet should be soaked ten or fifteen minutes in very hot water, an ice bag placed on the head and the following given internally:

℞. Phenalgin .....3ss 2|
M. Ft. cap. No. iv. Sig.: One every two hours.

In rheumatic headache the following:

℞. Phenalgin .....gr. v |30
Sodii salicylatis .....gr. x |65
M. Ft. chart. No. i. Sig.: One such three times a day.

In uremic headache the diet should consist of milk; the bowels kept regular by salines and diuresis encouraged by digitalis, caffein or the vegetable salts of potassium, as follows:

℞. Potass. citratis .....3ii 8|
Spts. juniperis .....3vi 24|
Spts. etheris nitrosi .....3ii 8|
Inf. scoparii .....℥vi 180|
M. Sig.: One wineglassful three times a day.

In neuralgic headaches the following:

℞. Acetanilidi .....gr. iiss |15
Caffeinæ citratæ .....gr. ss |03
Sodii bicarb. .....gr. i |06
M. Ft. tablet No. i. Sig.: One such tablet every three hours.

Dysentery.

The following outline of treatment of dysentery in infants is recommended by J. F. Hay in *Med. World:* To an infant of eighteen months or older the following powder is given:

℞. Salol .....gr. xx 1|30
Bismuthi subnit. .....3iss 6|
Pulv. opii et ipecac. .....gr. vii |50
M. Ft. chartulæ No. xx. Sig.: One powder every four hours.

The mother is directed to give an enema of normal salt solution morning and evening, the amount given each time depending on the age of the child. The child must be kept on a light liquid diet.

If at the end of a week the stools contain mucus and blood, an enema containing grains 40 of silver nitrate to the quart of water is substituted for the normal saline solution.

Medicolegal.

Validity of License Tax on Healers.—The Supreme Court of Kansas holds valid, in the case of Steiner vs. Liggett, a city ordinance imposing a license tax of five dollars per day on magnetic, psychic or other healers, holding that there was statutory authority conferred on the city to require a license tax from any one engaged in the calling or profession of magnetic, psychic and natural healing.

Evidence of Physicians as to Testamentary Capacity.—The Supreme Court of Appeals of West Virginia holds, in the case of Ward vs. Brown, that evidence of physicians as to testamentary capacity is entitled to greater weight than that of non-professional persons, provided they have had personal observation and knowledge of the person whose mental capacity is in question; otherwise, it is not. Expert testimony, except under special circumstances, is entitled to only such weight as the jury may deem it entitled to when viewed in connection with all the evidence and circumstances; and it is error to instruct the jury that the evidence of physicians testifying as experts only, on the trial of an issue of whether there was a will or not, is entitled to great weight.

Department Superintendent Can Not Employ Physician.—According to the Supreme Judicial Court of Massachusetts, the case of King vs. the Forbes Lithograph Manufacturing Company was brought by a physician and surgeon to recover compensation for services rendered in caring for one of the company's employes, who was injured in the machinery at its factory, and was taken to a hospital, where the physician attended him. The only evidence relied on to show a contract of the company to pay the physician was testimony that a superintendent of the company's cartoon department, who was authorized to employ and discharge workmen, told the injured employe to go to the hospital to be treated, and said that all bills would be paid by the company. There was no evidence that this superintendent of a department was authorized to make such a contract as agent for the company, and the court says that it was very plain that his authority to hire and discharge employes did not give him a right to bind the company by a contract to pay for medical or surgical treatment of one of its employes. In those jurisdictions where railroad companies have been held liable for medical attendance procured for an employe by one of their agents, the liability has been limited to cases in which there was an extreme emergency calling for immediate medical or surgical attendance. In this case there was no evidence to warrant a finding that there was an implied contract on the part of the company to pay for such services, and it was not contended that the undertaking of the superintendent was ratified.

Power of Executive Officer to Employ Physician.—The Court of Appeals at St. Louis, Mo., says that the case of Hasler vs. The Ozark Land and Lumber Company was brought to recover a balance of $135 for professional services rendered in medical attendance on and treatment of two employes of the company, during their affliction with smallpox. But it holds that the case did not fall within the well-established rule sought to be invoked by the company, that unless such relation exists between the party requesting a physician to render professional services, and the patient, as raises a legal obligation on his part to call in a physician and pay for his services, the law will not create by implication a promise to pay the reasonable value of the services thereafter performed, and such relation can not be claimed to exist between employer and employe. The testimony in this case disclosed that the physician had declined attendance on the employes until the vice-president and general manager of their employer had directed him to render the services, and agreed to pay therefor. The evidence also showed that the physician had received $40, which he claimed was in part payment, but which the company claimed was a personal loan by the official advancing it, though it was conceded to have been paid from the company's funds, and without any acknowledgment or obligation therefor given back by the physician. The testimony of the physician, the court holds, entitled him to have submitted to the jury the issue of his employment by the company to render the services performed; and it affirms a judgment in his favor. It also holds that an instruction that the jury might presume that the executive officer of a business corporation, at once its vice-president and general manager, had authority to make the contract on behalf of the company to which the physician testified, under the conditions presented by the record, was proper. The case was one essentially for the determination of a jury.

Examination Under Policy—Negligence—Removing Cast.—The Supreme Court of Appeals of West Virginia holds, in the case of Tompkins vs. the Pacific Mutual Life Insurance Company, that only a right of examination as to an injured person entitled to a weekly indemnity under an accident insurance policy is conferred on the company issuing the policy, by the following clause contained therein: "Any medical adviser of the company shall be allowed to examine the person or body of the insured in respect to any injury or cause of death in such manner and at such times as he may require." The court says that also confines the authority of the company's agent (medical adviser) within the same limit. That right of examination, and the agent's authority, however, extend to the making of the examination "in such manner and at such times" as the agent may require. It confers no right to treat the injury, and the insured is not bound to submit himself to any course of treatment at the hands of any physician that the

company may indicate. If he had bound himself to that, the obligation would have carried with it his voluntary submission to the ordinary risk to which the law holds all persons who submit themselves to treatment at the hands of physicians, and he could make the company liable only on such grounds as would enable him to recover damages from a physician employed by him. In such case a physician is held to the exercise of such care, skill, and diligence as are ordinarily possessed by the average members of the profession in good standing in similar localities, regard also being had to the state of medical science at the time. This construction of the clause quoted, the court further holds, undoubtedly creates the relation of master and servant between the company and its medical adviser in the exercise of such right of examination, and the company must answer for injuries resulting from the negligence or misconduct of its agent in the premises. Though the insured is not bound to submit to such examination, and may refuse at the risk of loss of his indemnity, or of litigation on account of his refusal, he may submit to it without losing his right to exact care and skill in its exercise; and it is no defense to his action that he consented to examination in a particular manner, if he did so in pursuance of a request or demand that it be so made. Between the physician and the insured, in such case, the law governing the relations of physician and patient does not apply. Where the injury of the insured is a sprain of the foot, requiring a plaster cast or similar appliance to hold the injured ligaments in place until they heal or regain strength, and the agent, in making the examination, removes, and fails to replace, such appliance, and injury results therefrom, he is guilty of negligence for which his principal must answer in damages. Referring particularly to the case before it, the court says that, having the right to examine in such manner and at such times as it saw fit, the company did no unauthorized act in removing the plaster cast, if its removal was necessary or desirable in making the examination, and not injurious. As to this there was no controversy. Nor did it seem to be disputed that, in the absence of directions or assent to the contrary, on the part of the insured, it was the duty of the company's agent to replace the bandage. Clearly it was, for by leaving it off the status was changed, and no right to make such change was given by the contract. In a sense, that would have been going entirely beyond a mere examination, and performing a work in the nature of treatment of the wound.

4 *The Present Status of Subconjunctival Injections in Ophthalmic Therapeutics. Charles S. Bull.

2. **Albuminuria.**—Six cases of albuminuria are reported by Schroeder, who holds that it is impossible to determine whether albuminuria is a premonition of further trouble until the case has been kept under observation for some time. Transient albuminurias are not of serious import unless they recur too frequently. Persistent and even cyclic albuminurias should cause anxiety, and the physician should ascertain the cause and act accordingly. As a rule the earliest indications of Bright's disease will be found in the urine. Careful observation of these cases means frequent examination of twenty-four-hour specimens to find out the daily quantity, the amount of urea, the specific gravity and the presence of albumin and casts. The blood vessels and heart should receive attention. These observations may have to extend over a period of months or even years. The most frequent causes of albuminuria are excessive eating, over-indulgence in alcoholics, possibly tobacco, mental and physical stress and the gouty diathesis. The mortality among albuminuria cases is great, not only because of its association with chronic nephritis, but also on account of the poor resistance to other diseases.

3. **The Body Weight.**—Einhorn discusses the methods and indications for increasing or reducing the body weight. Physicians are frequently called on to treat emaciation and also the leanness of the healthy, which, if of too high degree, should be combated. Such persons have no reserve fat to fall back on. He holds that in 90 to 95 per cent. he has been successful in raising the body weight where he has tried it. We should inquire into the amount and quality of the food taken; how it is taken. If it is insufficient, it should be prescribed in larger quantities. If a beverage is taken at meals it should be more nutritious. In suitable cases two or three smaller meals, consisting of milk and buttered bread, may be given with advantage. It is advisable, he says, to prescribe the daily amount of butter that should be taken; he usually orders a quarter of a pound a day. The success of treatment is practically assured, if it is possible to take larger amounts of food. He thinks a glass of cold water during eating has a stimulating effect on the appetite. Outdoor life and moderate exercise are of great value. By the successful addition of food and exercise we have not only an increased formation of adipose, but also of muscular tissue and gain in strength. The body weight should be reduced as soon as there is a surplus of fat, which is displeasing to the eye or mars the harmony of the body. There are two ways: diminishing the amount of food or increasing the amount of work, or a combination of both. Practically, he says, we should proceed to determine exactly under what dietary an individual remains in a state of bodily equilibrium. If he has not gained, you may take the amount of food he has been taking as the standard, but if he has gained on it, it should be diminished. The weight of the patient should be controlled every two or three days. As soon as the amount of food necessary to keep a proper equilibrium has been determined, we must begin slowly to increase the muscular work, never allowing the patient to become exhausted. The accelerated heart action and respiration must return to the normal ten minutes after beginning to rest. If this is not the case, the work must be reduced. By the methods here employed the fat is distributed where it will not interfere with muscular action.

4. **Subconjunctival Injections.**—Bull's article is almost entirely a review of the work and the recommendations of others. From an examination of all the papers and cases reported, he concludes that the efficacy of the solution injected can not be ascribed to local acceleration of the lymph currents, the so-called leucocytosis, nor to the antiseptic action of the remedies employed, since the presence of such processes can not be demonstrated in the tissues of the eye after injection. The chief change seems to be in the composition of the aqueous humor and the explanation of the action of the subcutaneous injections is to be sought in their local irritating properties. A careful observation of his own cases has not convinced him that subconjunctival injections bring about any more rapid or favorable results than other methods of treatment, excepting in cases of orbital cellulitis of an infectious character where injections of a sublimate solution did have a favorable effect in hastening the suppurative stage and reducing the infiltration. He thinks all reports of the beneficial effects of subconjunctival injections should be carefully criticised and compared with the results obtained by other methods of treatment before accepting them as of any real value.

9 *Subconjunctival Medication, with Special Reference to the Use of Salt-sugar Solution in Acute Affections of the Anterior Portion of the Eye. Howard McI. Morton.
10 A Case of Black, Hairy Tongue. R. H. Johnston.
11 The Temperature in "Summer Complaint." William F. Waugh.

5. **Immunity in Tuberculosis.**—Trudeau reports his experiments which, like those of de Schweinitz, antedated those of Behring. He has used only small animals, guinea pigs and in these he has not obtained an absolute immunity that will protect overwhelming infections, but still they show that the latter condition is not comparable with ordinary exposure in every-day life. He thinks the principle has been established and that with a more thorough knowledge of it we may yet get considerable immunity. Behring has shown an absolute protection of calves and if we can only do as much for babies one of the greatest problems of the medical profession will be solved.

6. **Gastrotomies for Foreign Bodies.**—Friedenwald and Rosenthal analyze the published cases of gastrotomy for foreign bodies in the stomach, showing that it is best to remove them as early as possible by gastrotomy as delay may produce serious gastric disturbances and make further operative procedure more difficult and serious. They give a tabulated statement of some ninety cases from the literature.

9. **Subconjunctival Medication.**—Morton advocates the use of physiologic salt with 3 per cent. sugar solution added for subconjunctival injections. Its use thus far has been confined to cases of pneumococcus ulceration of the cornea, to forms of plastic iritis associated with rheumatic disease, traumatic infected ulcer of the cornea and dendritic ulceration. In all these classes of cases it has been his regular practice to use injections of 2 to 4 grams, or even 6 grams, of salt-sugar solution, using the ordinary hypodermic syringe with a capacity of 1 c.c. and filling the subconjunctival space about the corneal margin entirely. This necessitates the introduction of the syringe at several points just anterior to the insertion of the recti. In sthenic individuals with one eye alone involved, the injection of a large amount of fluid subconjunctivally is the best procedure, to be followed by slight pressure from Liebrich's pad, and the patient is directed to use hot fomentations for periods of five minutes with half-hour intervals. He has never yet seen an eye suffer from this operation. The injections were preceded by the instillation of a 4 per cent. solution into the cul-de-sac, thus causing but little or no pain. He thinks the use of subconjunctival injections is limited to the more severe and intractable cases. Ordinarily the office methods are sufficient for the common forms of disease involving the anterior ocular segment, but he does believe that this method of medication assists in promoting resolution more rapidly in certain intractable cases than the usual local measures.

12 The Sources Favoring Conditions and Prophylaxis of Malaria in Temperate Climates, with Special Reference to Massachusetts. (To be continued.) Theobald Smith.
13 *Subparietal Injuries of the Kidney. (Concluded.) Francis S. Watson.

13. **Subparietal Injuries of the Kidney.**—In this conclusion of his paper Watson gives an account of 6 personal cases and discusses the treatment. He first calls attention to the high mortality with expectant treatment and the low mortality in the series operated on otherwise than by nephrectomy. Hemorrhage is the factor which needs the most attention, and the source of it should be at once sought for by laparotomy when it announces itself by the presence of free fluid in the peritoneal cavity or by other signs of progressing hemorrhage. The details of operative treatment are given rather fully. The first fundamental principle is to save the kidney, or as much of it as possible, and make only a partial nephrectomy if only a portion of the organ is damaged, closing the kidney wound by suture. If one has to choose whether the spleen or kidney is to be removed, let it be the spleen. In liver involvement the tampon and suture are appropriate and often successfully used. In uncomplicated cases, not presenting any evidence of progressive hemorrhage, a question as to expectant treatment may be raised. In the great majority, where the hematuria is of short duration, or slight if of long duration, and when it is not secondary, and when no signs of progressive hemorrhage are shown by the patient, expectant treatment may be employed. Otherwise, operative treatment should not be delayed. The conditions that call for prompt surgical treatment are sudden disappearance of blood from the urine if accompanied by pain and the appearance of tumor or increase in the size of an existing tumor, showing that the pelvis or ureter has become blocked; also retention of urine in the presence of clots as well as the signs already mentioned. In regard to the danger of infection, surgical intervention seems to be indicated, he thinks, when there is a tumor in the loin which does not subside within a reasonable time, say a fortnight; when the bladder is already infected or becoming so, or is liable to become so from the necessity of frequent catheterization, as in prostatic obstruction, and when there is retention due to blood clots; lastly, if there is any reason to suspect previous existence of such diseases of the kidney, as tumors, calculus, pyelitis or pyelonephritis. He finds but 7 cases in the literature where suture of the kidney has been performed, or 8 including the one here reported. He thinks that while his case and one other were unsuccessful, it is worth while to apply the suture in such cases as are amenable. As regards the lumbar and abdominal routes for nephrectomy, he finds the death rate only slightly higher in the latter, and when we leave out complicated cases the figures are even more favorable for the abdominal route. As regards the decrease in the death rate of the two operations during the past thirty years, it has been apparently much greater with the latter than the former.

18 *Treatment of Eclampsia. William Krusen.
19 Scarlatinal Arthritis. E. Paller.
20 A Season of the Pioneer Resident Physician in the Yosemite Valley, 1901. Charles V. Cross.

14. **Diseases of the Gall Bladder and Bile Ducts.**—Ewald's article discusses the diagnosis, more particularly of the diseases of the gall bladder itself, noticing the symptoms of colic, icterus and tumor. In conclusion he remarks in regard to treatment, holding as regards operation that the circumstances are comparable to those of appendicitis, but in case of gall-bladder disease operations are much more difficult and more severe in their consequences than those of the appendix. During the acute inflammatory stage he advises treating the colic by the known means of relief and in addition washing out the stomach with hot water or with a solution of nitrate of silver (Ehrlich), or the drinking of large quantities of hot water. In severe acute infections immediate operation is advised. In patients with rapidly recurrent favorable attacks he prefers internal treatment; in unfavorable cases with recurrent attacks he advises operation. In cases of long standing obstruction or compression jaundice he advises operation according to the individual case. A positive diagnosis of compression jaundice indicates immediate operation. On the other hand, in cases of obstruction jaundice by stone he believes that if the patients can take care of themselves properly and use no extra exertion, operation may be delayed for some time. The fact that healing of the wound after operation has so many threatening circumstances, leads one to wish to spare the patient the ordeal as much as possible. In any case preventive means against recurrences should be employed.

15. **Diseases of the Skin.**—The importance of diet in relation to skin diseases is emphasized by Bucknall, who thinks that the quantity of the food, as well as its quality and method of giving and the time at which it is taken, may all be of importance. There is no universal table of diet in these cases. Carbohydrates in excess are injurious; pastry should be especially avoided. Alcohol is harmful even in small quantities in many skin diseases. Tea frequently does harm; coffee and coca are less injurious, but should be taken in moderation. He has no doubt as to the harmful effect of tobacco in certain cases. The climate and air also have their influence and too frequent washing, depriving the skin of its fat, may have some bad effect. The common notion that suppression of diseases of the skin is injurious has no definite facts for its

support. It is probably based on the observation that in some cases of eruptive fevers if the rash does not come out or recedes, the constitutional symptoms appear to be more severe. An accurate diagnosis is the very first essential. We must not imagine that when we know the cause the treatment that is most obvious is necessarily the best. As to external and internal treatment, one may be better in one case and another in another. He particularly speaks against the routine use of arsenic, which will always aggravate skin diseases of the acute type. It is of value only in cutaneous diseases of the scaly character, psoriasis, lepra, etc., and then requires careful watching to obviate the destruction of red blood cells. Baths are often of value. There is a risk of absorption by the skin of substances from the bath, therefore they should never contain anything that might be dangerous to absorb. Permanent baths are but little used in this country, though they are occasionally of great use. They are troublesome to manage, however, and of but limited application. In parasitic or fungoid diseases of the skin when baths are advised, he prefers for the medication the albuminate of mercury which if absorbed is not harmful. Ointments are most frequently prescribed, but they are uncleanly and may often be replaced by other applications. When there is a profuse secretion from the skin lotions and dusting powders are advisable. The author speaks of dymal (salicylate of didymium), recommended by Kopp, in certain forms of dermatoses, eczema, psoriasis, etc. He has seen it do excellent work in weeping eczema. As the skin disease varies from time to time it will be necessary to alter the local treatment and its application. It is better, he says, to have in mind the therapeutics of a few substances and the best means of using them than to be making hasty inconclusive trial of every new preparation or treatment that is devised.

16. **Anal Tuberculosis.**—The reason why there is not more intestinal or rectal tuberculosis is briefly discussed by Adler, who thinks it is possible that the gastric fluids may be destructive to the germs, and it is only when they are in excessive numbers that these parts are attacked. He suggests a treatment on this basis, that is, the use of essence of pepsin, acidulated with 2 drops to the ounce of a strong nitromuriatic acid applied directly to the ulceration either with the atomizer or on gauze left in contact with the parts. Systematic treatment by the use of some of the other remedies was also usually employed. His experience thus far with two cases has been sufficiently encouraging to warrant the mention of the matter, but he can not speak with authority as to the final outcome.

17. **Leukemia.**—From a general discussion of the subject, Nichols concludes that heredity, trauma and precedent disease conditions may have a causative influence, but are of only subsidiary etiologic moment in leukemia. Almost nothing is positively known as to the specific primary cause. A nervous origin has been suggested. Aside from this, the best explanation seems to be limited to: (*a*) That it is due to a vice in the internal processes of cell life and division that comes into generalized activity and results in exaggerated leucocytic hyperplasia; (*b*) that it is due to the action of toxic substances, autogenous or of parasitic origin; (*c*) that it is of infectious or parasitic origin, the parasites acting by the production of toxins or otherwise. Only the latter has been subjected to investigation and a considerable amount of bacteriolytic evidence been accumulated, but barring three or four doubtful exceptions is entirely negative as to the etiologic association of bacteria with leukemia, or as to the transmissibility of the disease.

18. **Eclampsia.**—On general lines the treatment advised by Krusen is, first, prophylactic; observation of the condition of the urine, especially the amount of urea excreted, keeping up a healthy action of the skin and elimination generally. He rather endorses the suggestion of Nicholson as to the relation of the thyroid gland to eclampsia and the use of thyroid in medication, and holds that on a thorough investigation of the relation between the thyroid gland and pregnancy depends much of our future success in the management of pregnancy and eclampsia. For the treatment of convulsions he holds that chloroform is one of the most reliable agents, and during the intervals venesection is one of the most important measures, though it has somewhat fallen into disfavor. Personally he thinks it is better than veratrum viride. When the pulse shows high tension and the face of the patient is suffused or almost cyanotic, bleeding should be employed. The depressing effect can be counteracted and the unknown toxins diluted by normal salt solution injections, intravenously, subcutaneously or by the rectum. There is no more valuable addition to our therapeutic resources in the last decade than normal salt solution. For purgation to aid elimination, croton oil, calomel, or a saline may be administered; to secure results a high enema of magnesium sulphate, glycerin and water should be given. He does not favor prolonged packs or baths. A brief warm bath may have a soothing effect. Morphia has a useful place and there is an undoubted tolerance which allows the use of large doses. It has great power and rapid action in preventing repeated convulsions in certain cases. In the majority of cases the convulsions cease soon after the uterus is emptied, and if eclampsia comes on when the child is viable, then extraction becomes advisable. He would not, however, advise cesarean section, as has been proposed. It is only justifiable when there is some reason for it. He thinks if the patient is actually in labor, in the second stage, the immediate emptying of the uterus is indicated. Mechanical dilatation of the cervix and deep cervical incisions are the best plan of treatment. The sooner it is begun and completed the better the chances of recovery. The eclamptic woman is especially liable to infection after delivery on account of the manual interference and traumatism undergone. Extraordinary care should be observed during the after-care of eclampsia, along the ordinary lines, but with more rest and quietude and with more vigilant attention to all the excretory organs.

26 *Therapeutic Suggestions in Diphtheria. Louis Fischer.
27 A Report of a Case of Spina Bifida; Operation; Death. Charles Greene Cumston.

21. **The Care of Epileptics.**—Peterson reviews the history of the methods of care of the epileptic before the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.

22. **Epileptic Aura.**—Spratling's article is detailed and lengthy, giving a large number of the principal symptoms that may precede the epileptic attack, both psychic and physical. His experience leads him to believe that the more sudden, severe and complete the attacks the less likely is it to be preceded by an aura. The further the convulsion departs from the classic type the more common and distinct the aura. The symptoms of aura justify close and analytic study as contributing possible guides to the seat of the disease.

23. **The Daily Rhythm of Epilepsy.**—From the study of 150,000 seizures, Clark finds that there is a more or less definite daily rhythm in the epilepsies, in the early evening, the noontime and early morning, roughly dividing the twenty-four hours of the day into eight-hour periods. There are also smaller or secondary rhythms. The interpretation of the rhythm is explained on the basis of cerebral fatigue and the accumulation of waste products at these periods which produce autointoxication, and which in turn exhibits itself in seizures during light sleep and during the day when the loss of cerebral inhibition is greatest. Secondary and contributing factors are manner of living, diet, exercise, occupation, sedatives and the character of the epilepsy.

24. **Pathology of Epilepsy.**—Meyer criticises the methods of study and finds that the anatomic ideas of epilepsy have not as yet any very decided support by reliable data. There have been certain researches, however, in the last five years which

are fundamental, such as that of Prus, who shows that cocainization of the cortex makes fits by electrical stimulation impossible, thus indicating that stimulation of the sensory elements of the cortex is essential to start any fit. He also points to many irregularities in the irradiation of the discharge over the cortex, and shows that not only the pyramidal tracts, but the segmental motor paths are the carriers of the impulses from the cortex to the segmental nerve-complexes. Bier has also refuted Kocher's idea that intracranial pressure is the cause of the fits, as he did not produce them by sudden increase of the pressure by temporary strangulation, even in epileptics. The second line of research of importance is that of the relation of metabolism to fits, and here we have much confusion in experiments and their results. Meyer thinks, however, it would be fair to say that with attacks of epilepsy go expressions of an abnormal state of equilibrium, evidenced by malaise and abnormal metabolism. Autointoxication is not demonstrated. The explanation of the occasional toxicity of the urine and blood for animals is still wanting. He does not as yet place any too much value on the ideas of Bra or Ceni, whose brilliant experiments with epileptic serum have been noted. He calls attention in this connection to the important psychic factor in all the new methods of treatment of epilepsy. He thinks there is at present a large material of safe empirical facts which has led to improvement in the condition of epileptics and their management. There are still good chances for a better utilization of what we know. The pathology of scientific medicine has added little, and it does not seem to give much immediate promise. He concludes as follows:

1. The frequency of nervous lesions in epileptics is difficult to establish. The ordinary examination is too open to oversights, and must be very systematic in order to justify the verdict of negative findings. The great variation in the number of sclerosed cornu ammonis, diffused gliosis, small foci of softening quoted by various authors, is certainly, to a large extent, an expression of variable attention, a picture of the psychology of investigators rather than of the distribution of facts.

2. Concerning the chemical investigations, the same psychologic factor of personal interest is even more deleterious to a fair comprehension of the facts. The truism that observation of the rules of hygiene in every direction is a great factor in the management of epilepsy, is decomposed into innumerable currents of interests. Nothing short of unprejudiced and complete series of investigation will help us here, and also a much greater conservatism with complicated methods, such as the tests of toxicity, the results of therapeutics, etc.

3. All these conditions are difficult to attain except in sufficiently equipped institutions, for which funds should be made available by the state, and by scientific corporations, so that they may work free of the need of sensational results, create a sound basis in clinical work and systematize the investigation according to methods which can be admitted as safe and fruitful.

To what extent this had best be carried is a question requiring much judgment. The one thing is certain—and every move in this direction should receive credit and encouragement—that institutions should be given a chance and should even be put under the obligation of doing justice to medical observation, of promoting the medical interests of its physicians and of laying a good foundation of experience, such as the isolated practitioner can never get for himself. On such ground more delicate investigations will find a healthy soil.

26. **Diphtheria.**—The specific treatment of diphtheria consists in giving the required dose of antitoxin, which depends on the severity of the affection; in mild cases 1,500 units in a child from 1 to 5 years. It should be repeated if the effects are not noticed within twelve to twenty-four hours. A child 5 to 10 years old should be given 2,000 units when it is first injected, with the same repetition if required. With severe toxemia and marked general depression and large pseudomembranes in the throat at least 3,000 units should be injected in the beginning. Two or three injections may be required at twenty-four-hour intervals, depending on the pulse, temperature, condition of the swollen glands and microscopic condition of the throat. In laryngeal stenosis it is also well to give fully 3,000 units, repeating with 1,500 in twelve hours if the stenosis does not disappear within that time. In many cases the pure Klebs-Loeffler bacillus is not the only infection and streptococcic antitoxin serum will be required. In a few he thinks the bacteriologic findings will be a guide to treatment, based on scientific data. The ordinary shortcomings that are most frequently encountered consist of placing too much reliance on the specific nature of the antitoxin regardless of other vital necessities. The indication next to antitoxin is for restorative treatment; proper feeding is essential. When it is difficult to feed by the mouth, it is a good plan to let the stomach have a rest and depend on rectal feeding. It is always advisable to remove putrid mucus from the nose and throat and catarrhal discharges to prevent their poisoning the system. It is surprising to see what good results are apparent, he says, after cleaning the nose and pharynx. As regards the solvent action of local remedies, he has not been able to see its value, though 2 per cent. sulphurous acid has been used by him to advantage, and is better than peroxid of hydrogen. He has used inunctions of unguentum Credé into the cervical glands. Fresh air in the sick-room is important and oxygen is indicated when there is cyanosis. The best antipyretic measures consist in sponging with evaporating lotions such as alcohol and water or acetic ether, locally. Cold packs and flushing the bowel are serviceable in some cases. If there is pneumonia, nephritis or other complication it should be treated as though the disease existed independent of the diphtheria. He advises an examination of the ears, as otitis media will sometimes keep up a high fever until the drum is ruptured. Ten to 20 drops of sweet spirits of niter are valuable, given several times a day, and calomel in 1/10 to ½ grain doses, repeated several times a day, is a useful adjuvant. Stimulants should be begun early, strychnin 1/100 of a grain for children one year old, repeated four times a day and gradually and cautiously increased. Children tolerate large doses. He also advises Tokay wine, caffein and champagne to support the heart's action.

32. **Cancer of the Rectum.**—The progress that has been made in the treatment of cancer of the rectum and the various operations suggested are first noticed by Samuel, who remarks on the insidiousness of the onset and the lack of characteristic symptoms. His own experience leads him to regard as one of the earliest symptoms a sense of fulness in the rectum accompanied by a mucous discharge, first noticed by the patient as simply a liquid discharge, with occasionally a slight amount of blood. Stenosis may be the first sign which forces the patient to seek relief. Bloody discharges may precede it. Pain is a marked feature in the later stages. The prognosis is a gloomy one, hence the advisability of early examination of all irritating conditions of the rectum. He notices the operative methods which, in his opinion, give the best results. The operative cases are where the obstruction is not marked and the infiltration has not progressed beyond the rectal walls. Much will depend on the location of the growth. He thinks the greatest advance in the future will be based on the fact that in most cases operators will entirely obliterate all the bowel below the site of the excised portion, and abandon the idea of establishing a continuity of the rectum by bringing down the upper part of the gut and suturing it to the intact sphincter. He advises the following steps as essential: That an artificial anus be made or anticipated by doing a preliminary colostomy in preference to the more radical operation. This will permit better disinfection by irrigation, which improves the patient's condition. With the growth high up in the rectum he would be influenced by the late teachings of Quénu, Abbe and others, and select the abdominal route, extending the usefulness of the operative procedure in that it could be made more radical in attacking lymphatic involvement, and that the ends of the bowel, if possible, might be brought out at the time

of operation or an artificial anus established at once. In obliterating the distal portion we get rid of the danger of infection by offensive discharges and incomplete operation. With preliminary colostomy fecal defilement is gotten rid of. He has had no experience with the combined abdominal and sacral route, but is encouraged by the results of Quénu and Abbe. Two cases are reported.

35. **Surgery of the Hand.**—Spears advises in factory practice with injuries of the hand to use conservatism to the utmost. Let the preliminary dressing consist of sterile gauze and the blood present if the man has been working in iron. If a woodworker, it is advisable to wash out the fine dust. Gasoline or benzine is best for cleaning the surrounding area. The use of bichlorid should be done away with and suture material should be abandoned in injuries of the fingers. A sterile wet dressing is to be used where suppuration has taken place.

46 *Euphthalmin as a Mydriatic for the General Practitioner. Albert B. Hale.

37. **Septic Sinus Thrombosis Due to Ear Infection.**—Randall reports two cases of sinus thrombosis from otitis, one fatal, and argues for early operative intervention in these cases.

38. **Laparotomy Convalescence.**—The question as to how soon patients should get up after abdominal operation is discussed by Hardon and his experience in twenty cases of laparotomy where the patient was up within from one to four or five days is detailed. His conclusions are that early getting out of bed tends toward greater comfort to the patient, shortens the stay in the hospital, there is earlier general convalescence, less danger of adhesions, diminished expense to the patient or charitable institution, while it avoids muscular atrophy from disuse and facilitates nursing.

39. **Strabismus.**—According to Nance, the ideal treatment in strabismus includes the establishment of binocular vision, which can usually be brought about by early treatment and, in a large proportion of cases, only by persistent and painstaking efforts on the part of the physician and parents. Delay in treatment renders less probable a perfect cosmetic result and endangers the probability of normal vision. The use of atropin is indicated early and glasses in most of the cases as soon as the patient is old enough. The monocular occlusion pad and various orthoptic exercises are valuable adjuncts to successful management. A thorough skiascopic and ophthalmoscopic examination by a competent ophthalmologist should precede the use of glasses. All astigmatism, as well as hyperopia or myopia, must be fully corrected and the correction ordered for constant use. Operative interference is justifiable and indicated after other measures have proven of no value, or in certain instances where the deviation is so extreme as to render inefficient ordinary orthoptic exercises.

42. **Streptococci in Scarlatina Serum.**—From experimental results with blood serum from scarlatina cases controlled by others with serum from normal individuals, Weaver and Ruediger conclude that neither normal nor scarlatinal blood serum possesses *in vitro* any appreciable bacteriolytic effect on the streptococci, and since normal blood serum exhibits no destructive action on streptococci it is illogical to ascribe terminal and other streptococcemias to any reduction in such action. The results obtained by using the colon and typhoid bacilli alone as indicators for the bacteriolytic complement serum can not be applied to other forms of bacteria, but each form must be tested separately.

51 St. Louis and the Exposition of 1904. Nelson W. Wilson.
52 Multiple Abscess of the Liver. E. L. Ruffner.

48. **Minor Gynecologic Operations.**—Goldberg summarizes his paper in substance as follows: All so-called minor operations, to be of permanent use, must be performed within at least one year from the time of beginning of the original lesion. After one year either the Alexander operation, trachelorrhaphy or curettage, or all combined, will be insufficient to restore the patient to perfect health. The reason for such failure in most cases is the involvement of the adnexa. The best course would be some operative intra-abdominal procedure, not by the internal inguinal ring method of Goldspohn, but by free incision, so that the exact conditions can be learned and properly treated.

59 Uremia: Shortcomings of Certain Urinary Tests. Merlin Z. Albro.
59½ Hygiene in Summer Complaints. William F. Waugh.

53. **Ovarian Transplantation.**—Martin reports two interesting cases where patients that had suffered from the loss of their ovaries came to him asking to have them restored. In each case he had the patient take a lodging near the hospital at which he was engaged, waiting for an opportunity to obtain fresh ovaries from some other subject. The operations were performed by transplanting portions of the ovaries which he had removed from other patients, into the broad ligament outside the horn of the uterus on either side. In both patients there was perfect recovery from the operation and signs of menstrual molimen, though no complete menstruation as yet. In both cases the ovaries had been removed long enough so that an artificial menopause had been thoroughly established and atrophy of the uterus had taken place. The preliminary operation had also destroyed the tubes or oviducts, making it necessary to reconstruct the oviducts from the atrophied remaining portions of amputated tubes and the horns of the uterus. The operation was unique in some ways in both cases, but he believes when sufficient time has elapsed for the atrophied uterus to recover its function, normal menstruation may occur. In both these cases there has evidently been a revivifying effect on the pelvic organs. Aside from the case reported by Glass, these are the only attempts that have been made to perform heteroplastic transplantation so long a time after removal of the organs. From his personal experience and a review of the literature he concludes as follows:

1. The operation of homo- or hetero-plastic transplantation of the ovaries in women or lower animals is no more dangerous if accomplished aseptically than any other small plastic operation on the appendages. (Morris, Dudley, Fish, Griegorioff, Frank, Arendt, Ribbert, Rubinstein, Glass, Mauclaire, Amico-Roxar, Monprofit, Foa, Knauer.)
2. Homotransplantation of ovaries in women or lower animals will prevent the atrophy of the genitalia which usually follows castration. (Morris, Dudley, Fish, Griegorioff, Knauer, Lukaschewitsch, Foa, McCone, Mauclaire.)
3. Heterotransplantation of ovaries in women or lower animals will prevent the atrophy of the genitalia which usually follows castration. (Glass, McCone, Mauclaire, Schultz.)
4. Transplantation of ovaries from one species into another may result in preventing the ordinary changes in the genitalia resulting from castration. (McCone, Lukaschewitsch, Schultz.)
5. Menstruation will continue in women and monkeys after homoplastic transplantation of ovaries. (Morris, Glass, Dudley, Frank, Mauclaire, Martin, Halban, in monkeys.)
6. Conception has followed homotransplantation in animals. (Griegorioff, McCone, Amico-Roxar, Mauclaire.)
7. Conception has followed heterotransplantation in animals. (McCone, Mauclaire.)

8. Conception has followed heterotransplantation of the ovaries in women. (Morris, Frank.)
9. Transplanted ovaries in other localities than the normal will maintain their vitality, functionate and prevent the ordinary sequelæ of castration.

54. **Perineal Prostatectomy.**—The operation and its variations for the enlarged prostate are reviewed by Murphy, who concludes that the perineal route gives the best ultimate results and is accompanied with less danger than the suprapubic or Bottini operations. As regards hemorrhage, sepsis, injury to the neighboring parts and danger to life, this operation is the best. The drainage is excellent and it favors rapid restoration of the bladder, while the period of wound repair is much shorter than by the suprapubic route. All his cases had primary union down to the drainage tube. The vesical control is almost uniformly good, and while the sexual power is destroyed, the relief of vesical irritation is great and the frequency of micturition is reduced to about normal.

55. **Elephantiasis.**—Johnstone reports the case of a patient with elephantiasis due to the *Filaria sanguinis hominis* as shown by blood examinations, though the patient had never lived in any region where this parasite is supposed to abound. The disease, she considers, had been acquired from a person suffering from filariasis who lived near her or from some mosquito infected with the bacilli brought from tropical regions in fruit. The inflammation and pain were relieved in this case by Lugol's solution, five drops three times a day.

57. **Hysterical Eye Affections.**—Gradle reviews the various forms of hysterical eye disorders, absolute blindness of one or both eyes being rarest, only about fifty cases being reported, either bi-lateral or mono-lateral. Both of his own cases promptly yielded to suggestion when observed in their incipiency. Hysterical exaggeration of visual imperfections is much more common, and he notices a singular phenomenon, named by Greef "tubular field of vision," in which when there is a contraction of the field of vision the absolute area of the field is the same, no matter at what distance. A double sight of one eye, not accounted for otherwise, is very suggestive of hysteria. Unless there is unequal refraction through different parts of the lens as determined by examination, monocular double sight may be always referred to hysteria. Other hysterical symptoms are pain and disagreeable sensations referred to the eyes, and most frequent of all is persistent winking. It is a mistake to call it chorea. He thinks it is generally a hysterical manifestation. The irregular action of the ciliary muscle is occasionally a troublesome symptom, but its frequency has been overrated. It is more common than true ciliary spasm.

58. **Iodonucleoid.**—Baum describes a new preparation of iodin made by Wesener, that he calls iodonucleoid. It is a reddish-brown granular powder, containing 9.5 per cent. of iodin in organic combination with nuclein, and he reports experience with its use. He has never seen any untoward effects in the 50 cases in which he has employed it, excepting occasionally a slight iodin acne. He thinks the good effects he has observed are due to the retention of iodin in organic combination in the system. It is non-toxic, 488 grains having been given in twenty-four hours, and twice as much iodin is retained and only one-fourth as much given as compared with potassium iodid, as shown by a study of its elimination made in connection with Dr. Wesener. Baum believes that this new organic iodid powder will enable us to give iodin in many cases where other preparations are not tolerated. It will accomplish all that has been claimed for potassium iodid without disordering the stomach or interfering with the general nutrition.

60 *The Prevention or Amelioration of Vomiting During the Administration of Chloroform. E. Stuver.
61 Homicide Committed While in the Amnesic State. S. D. Hopkins.
62 *The Essential Features of a Practical Medical Registration Law. S. D. Van Meter.
63 Dr. F. J. Baucroft. Edmond J. A. Rogers.

60. **Chloroform Administration.**—Stuver finds that painting the nasal mucous membrane with cocain solution before chloroformization does away with the complication of vomiting which is sometimes so troublesome. He uses a 2 per cent. solution applied on a cotton-wrapped probe ten or fifteen minutes before beginning to give the anesthetic. He thinks it will be equally effective with ether.

62. **Medical Registration Laws.**—Van Meter gives an interesting discussion of the subject of medical registration boards and laws. First the composition of medical boards is considered. He holds that they should be made up of reputable practicing physicians, irrespective of school or pathy, nominated by medical societies and appointed by the governor. The most important of their powers would be the revocation of licenses for other reasons than ignorance or incompetency. As regards examination, he thinks the greatest injustice is done by requiring men eminent in the profession to be examined. He holds that there are points of weakness in the plan and is inclined to think recognition of the medical diploma from a good institution better than examinations. The adoption of a high minimum standard of education for the colleges by the licensing board would be a great improvement. Too little attention is paid to the moral side of the applicant's qualifications; an investigation of former records should be instituted in every case. If laws are to accomplish anything they should be enforcible; there should be no politics in the boards. In conclusion, he emphasizes the importance of a proper wording of the law, especially as regards the definition of the practice of medicine.

68 Pain and Its Indications. E. C. Hill.

65. **Tuberculosis.**—Foss finds Hubbert's antistreptococcic serum of the greatest value in combating the secondary effects of pulmonary tuberculosis, and he thinks it is indicated in all forms of streptococcic infection. That it does its work thoroughly, he says, is a fact. In administering the serum he injects 20 c.c. subcutaneously between the shoulders, following daily with 10 c.c. and examines the sputum for streptococci at least every three days, continuing the serum until the streptococci are eliminated, usually after 60 to 120 c.c. have been administered. There is a reaction, sometimes a simple urticaria with itching, sometimes pain and swelling of the joints and nervous phenomena, varying with the amount of toxemia. In acute cases there is little or no reaction, but cases that have been infected for years show greater effects. He would not hesitate to use this serum in much larger quantities if necessary and recommends his confrères to give the substance a thorough trial.

72 On the Early Use of Solid Food in Artificially-Fed Infants. John W. Kyger.

69. **Malingering.**—Punton reports an interesting case of malingering in a young man 22 years of age who claimed to have been knocked down by the falling door of a freight car and to have become practically idiotic. The case was tried twice and a number of physicians testified as to their belief in regard to his disability. On the second trial, a few months ago, a verdict of $35,000 damages was given by the jury. Dr. Punton was called into the case, and with the chief surgeon of the road, Dr. Cale, alone maintained the opinion that the individual was simulating the disorder. Dr. Punton's opinion was based on the lack of physical evidence of paralysis, loss of sensibility, the condition of the reflexes, etc., which did not agree with the claims made, and he also did not believe in his assumed mental condition. After the second trial a prominent lawyer gave testimony that before the alleged accident the young man and his mother had consulted him as to

the possibilities of getting up such a case, and asked his professional aid. He had refused this to them, but kept the matter to himself until he saw that the case had progressed so far that it did not seem advisable to him to keep silent longer. The judge set aside the verdict and ordered a new trial, turning the patient over to the physicians for further investigation. He was kept in a sanatorium under observation, and his friends were not allowed to see him. On the pretense that he was to undergo a surgical operation for examination of his brain, he was etherized, and in the stage of excitement talked freely. A second experiment was also performed similar to the first, and he finally made a full confession, and is now with his mother under heavy bonds after indictment for attempt to defraud. The outcome of the case thoroughly vindicated Dr. Punton's opinion expressed from the first, and testified to in the trial. The case is of interest, as having aroused considerable attention in the state where it occurred, the amount of damages obtained in the second trial, and especially on account of the success of the impostor in keeping up his imposition so as to deceive so many skilled physicians for so long a time.

71. **Editorial Faults.**—Dr. Crother's paper refers to editorial laxities, etc., in medical journalism generally.

76 An Index of Diseases, Alphabetically Arranged, with Their Modern Treatment. (Continued.) G. Bjorkman.

73. **Chorea.**—Mettler finds that arsenic is a standby in chorea, understanding by this the true Sydenham's chorea, not the multiple affections that have been occasionally described under this name.

75. **Summer Diarrhea of Children.**—The principal points of Ratner's paper are summarized in substance by him as follows: Summer diarrhea is not a difficult disease if common sense is used. The best substitute for mother's milk is properly modified cow's milk. When the stomach is very irritable all food should be withheld for from twelve to thirty-six hours. The first step in medical treatment is to empty the stomach and bowels thoroughly. For this castor oil, plain or in emulsion, is best. The most harmless intestinal astringent for children he holds is tannalbin, and the best antifermentative is ichthalbin, which two drugs are valuable additions to our materia medica. After the bowel has been thoroughly emptied, opium in small, carefully regulated doses is frequently of the highest value. For antipyresis, sponging with cold or lukewarm water should be preferred to any internal medication.

77. **Strabismus.**—Roy's ideas in regard to the treatment of strabismus are orthodox. He believes in operation only as a last resort after other methods, such as glasses, atropia, etc., have been employed. Whatever operative procedure is used should be done with the same care as in any other major surgical operation.

78. **Our House and Our Servant.**—The subject of infection and sanitation of houses is first noticed by McHatton, who gives points from his own experience. The next question which he considers is the servant question, which in the South is a serious one. The deteriorating influences which have acted on the blacks of late years and their habits of life are remarked on. They usually live independent of their masters and mistresses, who, after their work is done, have no control over them. The dangers of communicable diseases are serious. The only escape he sees would be to encourage the servant's remaining in his former relations, living on the premises and allowing an inspection of his physical condition and material welfare. The other alternative would be to make a physician's certificate essential to his employment, having it renewed from time to time.

2. The Pressure Pouch of the Esophagus.—Butlin reports eight cases which indicate to him that this anomaly is by no means so rare as he at first thought. He reviews the symptoms characterizing the condition as published in a former article in 1898, namely, the return of fragments of undigested food at varying periods, even to a day or two after eating; the gurgling up of gas from the throat, particularly when pressure is made on the left side of the neck low down, which is especially distressing to the patient. There may also be a distinct bulging in this situation when food is taken, though this is not a constant symptom. A bougie is arrested about nine inches from the teeth, and if this is of curved metal, it can sometimes be felt through the skin at the posterior triangle of the neck, almost always on the left side. Other symptoms may be present, such as wasting, cough, etc. The operation is not more dangerous to life than a cure will justify. The method was described in his former article. He offers here the following suggestions:

1. In order to be sure that there is no stricture of the esophagus below the opening of the pouch, a bougie should be passed into the stomach from the mouth at the time of operation. If this can not be done before the wound is made in the neck, the pouch should be exposed, separated from the surrounding tissue, and drawn upward out of the wound. Then, with a little manipulation, a bougie can be passed over its mouth.
2. If the pouch is of long standing and of large size, a soft tube should be passed into the mouth and stomach and retained as long as necessary for feeding. If this is impracticable on account of the patient's resistance or otherwise, it should be passed over a guide every time food is taken. Otherwise the food will pass out of the wound in the neck. If this still can not be done, then the tube should be introduced into the stomach through the wound and retained there until healing has nearly finished.
3. The less the tissues below the pouch are disturbed the better, to avoid septic inflammation and so on.
4. No attempt should be made to close the external wound, however carefully the neck of the pouch has been stitched up. It should be drained by means of a soft rubber tube. On the other hand, it is very desirable to close the opening into the esophagus for, although the stitches always give way in three or four days, the surrounding tissues are by this time sufficiently recovered to render spreading septic infection much less probable.

The operation seems to produce a speedy, complete and permanent cure of the disease.

3. Appendicitis.—Mackenzie describes and explains the symptoms of appendicitis according to the distribution of nerves, etc., hyperesthesia, visceral muscle reflex, bladder symptoms, colic, etc. He points out that it may be difficult to differentiate appendicitis from other complaints. The commencing attack has been mistaken for lumbago, rheumatism and other visceral affections.

4. Vomiting During Rectal Feeding.—Rolleston and Jex-Blake report cases which have been observed where vomiting occurred during rectal feeding, and speculate as to its cause. They find a certain proportion, say about 27 per cent., of patients with gastric ulcer vomit when on an exclusive rectal diet. They think in some instances this may be due to oral infection, and in others may possibly be the reflex result of rectal injections.

6. Shortening the Large Nerves in Amputations.—Spencer points out from his notes of cases in the Westminster Hospital that where the practice of drawing out the large nerves and cutting off a piece has been omitted there has been an indefinite delay in the patient's recovery. Continuous pain in the stump prevents the patient from wearing an artificial limb and finally resection of the affected parts is necessary. The whole chronic trouble is connected with the nerves which are left too much exposed.

9. Lumbar Puncture.—The following conditions are enumerated by Rhodes as those in which lumbar puncture may be useful for the patient and practitioner. Each is illustrated by cases. 1. The relief of pain and headache, illustrated by a case of gliosarcoma, where the head pain was unrelieved by drugs. Removal of a couple of ounces of spinal fluid gave complete relief. 2. Coma is diminished. Consciousness may return after coma has been established by the increase of intracerebral pressure. A lumbar puncture may indicate the necessity or otherwise for operation. In several cases of post-basal meningitis, a child apparently dying has been tided over and ultimately recovered when lumbar puncture has been systematically employed, reducing the intracranial pressure. If properly used it may be of value in aiding in the diagnosis. It obviates the necessity of nasal feeding and other tedious nursing procedures. In cases of comatous conditions its relieves the brain symptoms.

11. Iodoform in Tuberculosis.—Connon reports two cases of tuberculous disease of the joints cured by injections of iodoform emulsion, according to Squire's formula. About a dram of emulsion was injected every other day into the joint affected, through the sinus, with an ordinary glass syringe. By keeping the nozzle of the syringe firmly against the sinus opening the emulsion was allowed to act on the joint for three to five minutes. The sinus was subsequently covered with a pad of dry double cyanid gauze, and left untouched until the next injection, two days later. In both cases there was a surprising and immediate lessening of the discharge and improvement of the general health. The pain caused at first was only temporary, and the patients have remained well.

12. **Tuberculosis.**—Bulstrode notices the theories of infection and the exaggerated popular ideas in regard to it. He considers tuberculosis only slightly communicable, and quotes sanitarium experiences. The frequent non-recognition of tuberculosis is also noted. He says, think of the revelation of the general application of the tuberculin tests. Statistics are given showing the relation of poverty to tuberculosis and the comparative slight incidence among the well-to-do. The relation of alcohol to the disorder is considered at some length; that there is an association would seem from the evidence conclusive. He thinks, however, that many of the alcoholic tuberculous cases are primarily predisposed by constitution. In insanity a very large proportion of the patients die from tuberculosis, particularly those within institutions. He thinks more attention should be paid to increase resistance and improve the condition.

15. **Gelatin in Aneurism.**—Four cases are reported by Rankin. He says that while the experience of so small a number is not enough for drawing conclusions, it shows that gelatin injections may with proper precautions be given subcutaneously with safety. They produce a marked and speedy decrease in all of the subjective and some of the objective symptoms of internal aneurism. This relief is only explainable on the theory of diminution of pressure effects by shrinkage in the aneurismal sac. This diminution in size accompanied with marked increase in the resistance of the tumor wall could be distinctly determined in three of the cases treated. The after histories of the patients so far as they can be obtained show that the beneficial results are permanent.

17. **Dental Hygiene.**—The importance of dental health to the community is shown by Newsholme, who gives figures showing the increased number of rejected recruits in England on account of defective teeth, also the statistics as regards the prevalence of dental caries in the different races at different periods. It is evidently much more common in civilized than in uncivilized states. While he questions and reserves opinion in regard to many of the alleged causes, he says the most important preventive measures are: 1. The teaching of hygiene should be compulsory in the senior classes of all elementary schools and the hygiene of the mouth be an important part of the subject. 2. The enforcement of daily cleansing of the teeth should be organized in all residential schools. 3. The medical profession can stimulate dental reform by examining the teeth of all children attended by them and inculcate the importance of regular cleansing and early attention to caries. 4. Every industrial and other school authority should employ a dentist to treat the teeth of children and organize methods of dental hygiene.

The Practitioner, London.

23 *Introductory Essay. T. Clifford Allbutt.
24 *The Occurrence of Gout in the United States. Thomas B. Futcher.
25 *Gout in the Tropics. Alexander Crombie.
26 *Gout as It Occurs Among the Poor. F. S. Toogood.
27 *On the Relation of Gout to Granular Kidney and to Lead Poisoning. Samuel West.
28 *The Causation, Prevention and Treatment of Gout. Alexander Haig.
29 *Metabolism in Gout, and the Need for Combined Investigation. I. Walker Hall.
30 *Notes Respecting the Dietary for Goutily-Disposed Persons. Dyce Duckworth.
31 *The Treatment of Gout in Its Various Forms. Arthur P. Luff.
32 *Balneologic Treatment of Gout, with Special Reference to Bath. Gilbert A. Bannatyne.

23 *et seq.* **Gout.**—This issue of the *Practitioner* is devoted to a symposium on gout, which is introduced by an essay by Dr. Allbutt, who summarizes in a general way the papers that follow.

24.—Futcher gives his views as to the occurrence of gout in the United States, where he thinks it is often unrecognized.

25.—Crombie points out the lessened occurrence of gout in the tropics, which he explains by a lowered tissue metabolism required to raise the temperature of the body to a smaller number of degrees and in natives to the less nutritious nature of their diet.

26.—Gout as it occurs among the poor is treated of by Toogood, who attributes it principally to beer drinking.

27.—The relation of gout to granular kidney is discussed by West, who thinks that, like lead, it may produce chronic changes in the kidney, but does not cause interstitial nephritis. The presence of a granular kidney, however, greatly increases the liability of the patient to gout on the one hand and lead poisoning on the other, or both together; likewise greatly increasing the gravity and risk.

28.—Haig reiterates his views as to the importance of diet in gout, which he considers is but a symptom of poisoning by flesh and tea.

29.—Hall's paper is on the metabolism of gout. He believes in repeated purin determinations in each case and holds that if the exogenous or endogenous purins are delayed or retained in the system, their dilution in the tissues by large quantities of water or harmless fluids offers the best assistance to the renal cells for effective excretion.

30.—The diet in gout is treated of by Duckworth, who considers it a matter of individual study in every case. Slight causes of any kind will excite the disease in those predisposed to it.

31 and 32.—Luff and Bannatyne end the series with articles on the treatment of gout and its balneologic management.

Journal of Tropical Medicine, London.

43. **Pseudo-Hemisystolia and Post-Mortal Hemisystolia.**—Hering presents arguments to prove that hemisystolia is a disturbance in the heart action which occurs only during dissolution and is absolutely incompatible with life. Two forms of hemisystolia may be observed in studying the hearts of animals, one ventricle continues to pulsate while the other has stopped beating; or one ventricle beats less frequently than the other. The first form is a phenomenon of commencing death, and is only observed in such circumstances. The other has never been observed by direct inspection except in the dying heart, and both the anatomy and physiology of the heart are against its occurrence except as an agonal phenomenon. He emphasizes the words "by direct inspection," as graphic tracings are unreliable in this respect, as has been proven in his Institute for Experimental Pathology. On the other hand, he claims that the bigeminal beat (Herzbigeminie), frequently deceptively simulates hemisystolia, and the clinical cases in which the latter has been assumed were in fact cases of Herzbigeminie. They might be classed as a pseudo-hemisystolia, but the terms hemisystolia and systolia alternans should be discarded from clinical terminology. The former is not a clinical phenomenon, and the latter has no existence in fact. He adds that the results of experimental research on the heart can be applied without hesitancy to man, as the anatomy and physiology of this organ is essentially the same in all mammals.

45. **Combined Tuberculin Treatment of Tuberculosis.**—Mitelescu lauds the advantages of combining hygienic and dietetic measures with the use of tuberculin, and shows by study of the metabolism that much more satisfactory gains are made with the latter than without it. He warns against febrile reactions, and insists on the necessity for small, but long-continued doses. He believes that as the tuberculin is a powerful stimulant for the cells it is indicated only in cases in which the cells are still capable of responding to a stimulus, therefore, only in the early stages of tuberculosis. By stimulating the cells to produce the specific substance and giving them abundant nourishment, they gain the upper hand in the struggle, which can be recognized by the retention of nitrogen. If too much tuberculin is given or if the cells have too little vitality to respond to the stimulus, the tuberculin merely aggravates the morbid condition of the cells, which likewise can be recognized by increased disassimilation. He tabulates the findings in several cases to illustrate his views, and cites statistics to confirm the efficacy of this combined treatment.

46. **Giant Growth.**—Wieting suggests that the connection between the testicles and the bone growth may be indirect. When the organism comes to maturity, the bone growth is arrested. If the sexual apparatus does not attain its normal maturity at the proper time, the bone growth continues unregulated until it dies out from exhaustion. This would explain the persistence of the epiphyses in eunuchs and the non-arrest of their skeleton development at the age corresponding to puberty in normal individuals. This would also explain a case of giant growth which Wieting reports in detail in a young Asia Minor giant of syphilitic heredity. The latter was probably responsible for the atrophy of the testicles observed, and the lack of the regulating influence from the testicles was possibly responsible for the excessive growth which commenced at about the age of puberty. The man stood 215 cm. tall, but, being somewhat stooped, he measured 225 cm. long (almost 9 feet).

48. **Tumors in Adductor Region.**—As an aid in differentiating these tumors Czerny describes the case of a forester who had articular rheumatism of the toes, extending to hip on same side and followed by a tumor in the adductor region which proved to be tuberculous osteomyelitis of the pubis with infiltration of the vicinity. The participation of the neighboring joint simulated a coxitis. Adolph has recently reported a similar case only with staphylococci instead of tubercle bacilli as the causal agents.

49. **Resection of Jaw.**—Tilmann extols the advantages of the Schroder Stoppany method of handling cases in which resection of the jaw is needed. A model of the jaw is made out of sheet aluminum, and, when the jaw is resected, the corresponding part of the model is resected and inserted in the place of the missing bone. This enables the wounds to heal without shrinking of the parts, and this temporary prothesis can be substituted by the permanent hard rubber prothesis at any time. Tilmann has thus operated on two cases and recommends that models of the jaw in three sizes should be kept constantly on hand.

52. **Bloodless Treatment of Dupuytren's Contraction.**—Lengemann reports from Mikulicz's clinic three cases cured or improved by daily local injections of 1 c.c. of a solution of 2 gm. thiosinamin in 4 gm. glycerin and 14 gm. distilled water. After the twentieth day the injections were continued once a week until 28 had been given in one case. The action of the thiosinamin was reinforced by warm baths, massage and passive movements.

54. **Babylonian Eye Operations.**—THE JOURNAL for May 30, page 1545, in a description of the Hammurabi code of laws, which date from Abraham's day, reproduced the cut of the surgeon's seal found in the excavations in Babylonia. The seal bears a representation of the instrument used in the operations on the eye to which the code refers. The abstract referred to above was of an article by Oefele, who is a student of the cuneiform language. Winckler translates the cuneiform text somewhat differently in his recently published work on the "Laws of Hammurabi" in *Der alte Orient*, 1903, 4. The word which Oefele translates cataract he calls tumor, cavity, fissure, and the instrument which Oefele entitles "scorpion awl" he translates "operating knife." Professor Magnus of Breslau has been studying the subject from the standpoint of comparative philology as well as of ophthalmology, and concludes that the operation in question was merely the ancient paracentesis first described by Celsus in the first century after Christ. In the same way as the Ancient Greek and Roman operators, the Babylonian surgeon unwittingly pushed the opaque lens to one side in operating to evacuate a supposed pathologic effusion. Oefele was therefore correct in calling the operation the removal of a cataract. It was in fact a depressio or reclinatio lentis, but none of the ancient operators were aware of this. The Assyrian-Babylonians, the Greeks and the Romans, and later the Arabians and others down to the close of the sixteenth century, all supposed that what they accomplished by their operation was merely the evacuation of a pathologic product. The severe penalty imposed by the Hammurabi code for loss of the eye, as mentioned on page 1545, must have caused the surgeons of those days to refrain from performing the operation very often. The code does not describe the technic or after-treatment, but Oefele has discovered a letter from a surgeon of the time of Sardanapalus, named Aradnana, which mentions that a wound in the cornea will heal under a plaster bandage in seven or eight days. We may assume, therefore, that the Babylonian surgeons conducted the after-treatment of these operations along this line. The excavations at Susa have demonstrated that the Greeks and Romans owed their knowledge of humoral pathology to the Assyrian Babylonians, and that it did not originate with Celsus as heretofore supposed.

55. **Study of the Sweat During Diaphoresis.**—Brieger tabulates the results of determination of the freezing-point of the sweat during different sweating procedures.

56. **Treatment of Incurable Vesicovaginal Fistulae.**—Rose sutures the vulva, closing it entirely, and diverts the urine and menstrual discharge through a large opening from the vagina into the rectum above the sphincter internus. The vagina tolerates the urine and the bladder the admixture of the menstrual discharge without trouble. His first patient, after complete recovery and with the rectal urethra working well, died with symptoms of uremia and lesions of tuberculosis were found in lungs and kidneys. The patient in his second case also died, not long after the successful operation, from extension of the carcinomatous lesions on account of which it had been undertaken. His third patient had been subjected to various operations during several years for a vesicovaginal fistula consecutive to rupture of the bladder, and was finally dismissed by the surgeons as incurable before she came under his care. He established the rectal urethra in four operations, and the patient for nineteen years since has been in good health, serving as maid of all work, the rectal urethra functioning perfectly. She writes that she has never had pains in the sacral region nor swelling of the feet. She urinates usually twice in the night, and menstruation never caused any disturbance. During all these years she has been perfectly well, except for a transient gastrointestinal catarrh at one time and tonsillitis at another. The rectal urethra functioned perfectly in all these three cases and constipation was the rule, never diarrhea. The autopsy in two cases also showed that the rectum was apparently normal, no ulcerations either in the rectum or bladder and merely a slaty discoloration of the rectal walls. He criticises Howard Kelly's method of operating on these fistulæ as a more serious operation. In regard to the abolishment of the sexual life by his method, he states that his three patients were glad to be freed from the danger of possible conception in their condition. He asserts that in America the tendency seems to be to still further perfect the technic of vesicovaginal operations, while in Germany the tendency is rather to perfect obstetric methods so that rupture of the bladder and fistulæ will no longer occur. He remarks that it is a peculiar feature of these operations in America that they are so often undertaken after gynecologic operations, especially after hysterectomy on account of carcinoma. When the uterus has been completely removed, the possibility of the loss of sexual intercourse is of much less importance. He explicitly warns against coitus for a year at least after any operation for even the simplest vesicovaginal fistula. He has witnessed a perforation that occurred in the course of a digital exploration by a professor of obstetrics in a recently-healed case of a fistula of this kind.

60. **Cancer Research.**—For ten years von Leyden has been conducting researches on cancer, and the authorities have now provided him with increased facilities for the work by erecting three "barracks" on the ground of the Charité Hospital, supplementary to the first medical clinic of which he has charge. One of the buildings is arranged for a laboratory and the others are wards with accommodations for twenty patients, but only such will be admitted as are past surgical aid. Von Leyden has long been a partisan of the parasitic nature of cancer, accepting the "cell inclusions" as the parasites. Richet and Héricourt, in 1895, were the first to announce that they had had encouraging results from treatment of cancer patients with the blood of dogs, asses and horses previously injected with an aqueous extract of cancer tissue. Jensen in 1901 reported that he had succeeded in curing cancer in mice by injection of blood from rabbits previously injected with cancer extract. He also succeeded in cultivating cancer by reinoculation through eight generations of mice. Similar experiments had been undertaken by von Leyden and Blumenthal on dogs with positive results, and they had applied the same curative measures to man. Several goats were treated for months with injections of carcinoma from the uterus, liver, mamma, etc., each animal receiving only one variety of cancer. After months of this preliminary treatment, the blood of the uterus-carcinoma goat was used for the treatment of a case of uterine cancer, and of the mammary-cancer goat for treatment of mammary cancer, and so on. These experiences of Jensen and von Leyden were duly chronicled in THE JOURNAL at the time they were published. The results were not conclusive but encouraging. The experiments of the latter were the first systematic attempts to differentiate the various kinds of carcinoma and to apply in treatment the laws of cytolysis and autolysis. Jensen also emphasized the necessity of differentiating the variety of tumor, although his researches were conducted with only one kind, adenocarcinoma, and only on mice. Von Leyden and Blumenthal have also been experimenting with crushed tumor cells on the principle of the tuberculin treatment of tuberculosis, always carefully differentiating the variety of the tumor. They believe that the still unaffected parts of the organism elaborate specific substances in response to the stimulus of the tumor substance, which on the one hand check the growth of the carcinomatous degenerated pavement and columnar epithelium, and on the other hand, produce substances which are able to dissolve the carcinoma cells. Control experiments with intact pavement and columnar epithelium from non-cancerous organs have not displayed any positive therapeutic influence to date. There is thus a marked difference between the results attained by injection with crushed tumor cells and injection of the corresponding intact, non-carcinomatous crushed epithelial cells. A third line of cancer research has been conducted in the clinic, the purely chemical study of the metabolism of cancer subjects. The results up to last year were published by Blumenthal in the *Klinisches Jahrbuch*. All this research is being actively prosecuted now on a larger scale.

61. **Hereditary Icterus.**—Pick describes a family in which the mother and three of the children exhibited icterus. He attributes it to some congenital communication between the lymphatic and biliary passages or to some congenital insufficiency of the liver cells, entailing paracholia. In conclusion, he reviews the German and English literature on the subject.

63. **Syphilis in the Mothers and Newborn.**—Mracek analyzes his experience with syphilis in the newborn with a profusion of details. He has become convinced that the earlier the fetus is infected the more serious the results. Neither the age nor the form of the maternal syphilis allows any positive dictum as to the outcome of the pregnancy. In 11 cases of non-proven syphilis on the part of the mother (and thus possibly paternal infection), the placenta was found pathologic in 9 instances. This fact is not a decisive argument in regard to the mode of paternal transmission, but is certainly worthy of attention. The protracted infecting power of the mother and its deleterious influence on the offspring impose energetic treatment of every pregnant woman, even when the syphilis is latent. He urges for collection of data in regard to cases of syphilitic mothers who have borne healthy children and also in regard to early abortions. The article is a valuable contribution to the pathologic anatomy and the clinic of hereditary syphilis, for which Mracek has been collecting material for twenty years. In 11 of the cases with early abortion or maceration of the fetus, not a trace of syphilis could be detected in the mother. In 22 others with syphilis probable but not certain, not a single child survived to term, as was also the case in 24 instances in which infection and conception occurred simultaneously, and likewise in 22 in which infection occurred shortly before conception. He tabulates these and various other groups, and discusses the alternating births of syphilitic mothers, the heredity of inveterate syphilis, and numerous other questions. His experience establishes that the virulence does not become attenuated with time, and that even in the latest gummatous stage the mothers may bear children virulently infected.

64. **Paroxysmal Hemoglobinuria.**—Kretz explains this condition on the principle of amboceptors and complements in the blood. The attack of hemoglobinuria, he suggests, may be due to an accumulation of the complement under certain influences in an individual already unduly loaded with amboceptors. The result is hemolysis with consecutive hemoglobinuria.

68. **Idiopathic Pernicious Anemia.**—In the case reported the patient, a man of 32, had been healthy until a gastrointestinal affection developed, followed in three months by signs of progressive and speedily fatal anemia. At the autopsy nothing pathologic could be found except in the alimentary canal. Krokiewicz ascribes the disease in this case to constant absorption of enterotoxins, first taken up in the portal vein and passing thence into the general circulation. He does not attempt to decide whether the destruction of the erythrocytes was due to the direct action of the absorbed intestinal toxins on the blood cells or whether there might not have been some special affinity between the toxins and the potash in the cells. During the fifty days in the hospital the blood never exhibited the picture of essential progressive pernicious anemia, no normoblasts nor megaloblasts, but only moderate poikylocytosis, modification of the stainability of the red corpuscles and a low proportion of hemoglobin corresponding to the diminishing numbers of reds which were at first 460,000 with 25 per cent. hemoglobin, and towards the last 240,000 with 9 per cent. hemoglobin. The leucocytes numbered 6,000 to 1,600, but behaved normally in every respect. Only Quincke and Grawitz have reported smaller proportions of red corpuscles, 142,000 and 200,000.

70. **Tests of Smoke of Asthma Remedies.**—Netolitzky has been experimenting with and analyzing the smoke of belladonna, hyoscyamus, *Datura stramonium* and *Lobelia inflata*, as remedies for asthma, in the form of cigars, cigarettes or smoked in a pipe. He was able to demonstrate both chemically and still more positively by directing a stream of the smoke on the eyes of rabbits, that the essential principle does pass into the smoke. The results were only faintly positive with the *Hyoscyamus niger*, and were puzzling with belladonna, but with the stramonium and the lobelia the effect on the rabbits' eyes was unmistakable.

80. **Operative Treatment of Hemorrhage After Tonsillotomy.**—Burkard cites the various methods of arresting threatening hemorrhage in these circumstances and describes in detail that practiced by the late Professor Nicoladoni. In the rare cases in which all other measures proved ineffectual he made an incision in the neck, commencing about 1 cm. below the ear and proceeding as if to remove a neoplasm in the tonsil, the lower jaw drawn up and the stump of the tonsil presented in the incision by pressure through the mouth. The tonsillar vessels are ligated, but the large vessels behind need not be touched. The styloglossus must be drawn up out of the way or severed. The tonsil lies directly in front of the insertion of the fibers of the stylopharyngeus in the swallowing musculature. The bleeding is carefully staunched, the pharynx opened, the stump of the tonsil extirpated and the pharynx closed immediately by suturing together the pillars of the fauces either through the incision or through the mouth. This intervention is more tedious and complicated than ligature of the carotid, but by observing the directions in detail, it can be rapidly done and is a much less serious operation than ligating the carotid, while it ensures arrest of the hemorrhage with much greater certainty.

81. **Physostigmin in Post-Operative Meteorism.**—Moszkowicz has found this drug magical in the relief of post-operative paralytic ileus. His experience includes five cases. He expatiates on the dangers of this pseudo-ileus which is one cause of death after laparotomies, and has also been observed after herniotomy and vaginal operations. The autopsy discloses that the peritoneum is intact and that the trouble is evidently the result of a vicious circle, venous hyperemia, edema of the intestinal wall, paralysis of the intestinal musculature, meteorism and disturbances in absorption. This vicious circle can be broken up by physostigmin. In his experience a subcutaneous injection of .001 gm. of the physostigmin salicylate was well tolerated by 3 extremely debilitated patients. In the 2 other cases this amount was given in two doses. The extreme distension of the intestines was promptly relieved, and in 2 of the cases the measure was life saving. No disagreeable by-effects were noted in any organs. The blood pressure was distinctly increased, the drug acting on the heart action like camphor.

82. **Serum Treatment of Scarlet Fever.**—This communication was presented at the Madrid Congress and the nine diagrams give an oversight of the effects of the treatment in the 112 cases in which it was applied. None of the children died that were injected on the first and second day of the disease, although there were 8 very severe cases in the 24 injected the second day. Only 17.4 per cent. died of the 23 injected the fourth day, and 30 per cent. of those injected the fifth day, after which the mortality rose to 50 per cent. of the 4 not injected until the ninth day, the latter all very severe cases. A single, large injection the first or second day affords the best results.

83. **Sign of Rachitis.**—Neurath gives a photograph of a chubby hand in which the fingers show marked deformity of

the bones, the phalanges appearing to be swollen, giving the fingers a spindle-shaped appearance between the joints. He has observed it only in rachitic children, and usually in those under a year old. When noted in older children the rachitis is always in a severe form. He was never able to discover the lesion in non-rachitic children or in those only slightly affected. It was always accompanied by enlargement of the epiphyses and ends of the ribs. He found that he could diagnose rachitis in children before examining them elsewhere, by merely feeling for the spindle-shaped enlargement of the phalanges. It subsided under "phosphorus cod-liver oil" in conjunction with the other symptoms of the rachitis.

86. **Cell-Division Under the Roentgen Rays.**—G. Schwarz of Vienna reported at the local medical society that he had been studying the influence of the *x*-rays on living sea urchin's eggs. In no instance was it possible to detect any inhibiting action on the part of the rays on the normal cell division. These and similar researches on other animal tissue have convinced him that the inhibiting influence of the rays which Lopriores has established in respect to plant cells, does not exist in respect to animal cells. The influence of the rays on tumors, therefore, can not be explained on this assumption. He thinks the action of the rays may possibly be explained by assuming that they render certain substances, especially albumin, insoluble. The phenomena observed with the *x*-rays, Finsen light treatment and exposure to the sun for hours on a glaring snow field, may all be of the same nature, i. e., the rendering insoluble of certain metabolic products in the cells whose further elaboration and elimination are thus hindered. This stoppage gives rise to the chronic affection following a period of incubation which we designate as solar erythem and Finsen and Roentgen dermatitis. The sea urchin's eggs were exposed to *x*-rays which blackened a photographic plate under the same conditions in less than a minute.

88. **Yohimbin as an Anesthetic.**—A recent death at Vienna after the use of cocain causes surgeons to be specially interested in the newly-discovered anesthetic properties of yohimbin. Strubell found that the local application of a 1 per cent. solution induced undoubted hypesthesia to anesthesia in the upper air passages, amply sufficient for operations that did not go very deep into the tissues. This application is absolutely harmless and does not blanch the tissues, but induces a moderate hyperemia without contraction of the tissues or severe primary hemorrhage at the time or later. He suggests that its combination with adrenalin might prove especially advantageous for rhino-laryngologic work.

90. **Roentgen Treatment of Tumors.**—Exner reports 3 cases of inoperable mammary cancer unmistakably benefited by the *x*-rays. In one case the lesion apparently healed. In a case of melano-sarcoma the cutaneous metastases were treated by the *x*-rays and many of them subsided under their influence.

92. **Phosphorescent Power of Radium Rays.**—It has been asserted that totally blind persons are able to see the radium light. They not only perceived the phosphorescent radium screen, but were able to distinguish the silhouettes of coins, keys, etc., placed on the screen, the same as a seeing person. Holzknecht and Schwarz think these facts can be explained in two ways: Either the radium rays passing through the tissues reach and irritate the optic nerve and stimulate the relics of vision left in it—in which case the sound eye would also experience the same tendency, and the blind person, after a little practice, might be able to perceive any dark object on a bright background. Tests in this direction have already been made, and Heller reported two years ago that it is possible to save some degree of vision by exercises of this nature. The same results can be attained with any light, and the radium has nothing specific to do with the phenomenon. It was observed with the Roentgen rays and interpreted in the same erroneous manner at first. The other, and the correct explanation, they believe, is that the phenomenon is due to the transformation of the energy of the radium rays into objective phosphorescence. This power of inducing phosphorescence in other bodies is possessed by the radium rays to a remarkable extent. No screen nor chemical is required; any animal tissue whatever, hairs, bone, muscle, a drop of water, a scrap of sugar, but especially the human epidermis, are rendered more or less vividly phosphorescent under the action of the radium rays. They believe that no one else has called attention to this property of radium. This explanation of the vision induced in the blind by radium is confirmed by the localization of the phenomenon. When the radium is applied to the right, the visual sensation is on the right side, applied to the left, above or below, it is respectively on the left or above or below to correspond. The radium rays evidently render the sclerotic phosphorescent, and this phosphorescence is seen by the point of the retina opposite to it. When a visual sensation is experienced from compression of the eyeball, the source of the light is referred to the point opposite that from which the light compression proceeds. This is directly the reverse of what is experienced from the radium.

93. **Theory of the Period of Incubation.**—Pirquet and Schick relate clinical and experimental researches which demonstrate that an organism reacts more promptly to a renewed infection or intoxication than it did the first or previous times. That is to say, the incubation period is shorter. They theorize from this fact that the pathogenic substance has *per se* no power to induce the consecutive sickness. This follows when the organism has had time to elaborate certain products under the influence of the pathogenic substance, which in turn modify the latter. When this modification has reached a certain degree the symptoms begin to appear.

101. **Radium Treatment of Carcinoma.**—Exner exhibited from the late Professor Gussenbauer's clinic a case of carcinoma of the mouth and two of melano-sarcomata, at the meeting of the local medical society, June 26. (See editorial, The Journal, July 11.) Each had been treated with the radium rays, applying the radium in a capsule fastened to the spot with adhesive plaster. One melano-sarcoma had been removed three years before, but numerous small metastases had been noticed for eight months, shimmering black through the skin. These nodules were treated once each with the radium for five to twenty-five minutes. A dermatitis followed, the redness first perceptible after two to forty-eight hours. None of the nodules showed much change that had been treated for only fifteen minutes or less, but all the others grew perceptibly smaller, and some of them retrogressed completely. The nodules disappeared before the superficial tissues exhibited the necrosis from the action of the rays. In one case an epithelioma at the corner of the mouth recurred after three operations three and six years apart. The outer surface formed a protruding ulcer about the size of a quarter, that could be palpated as a hard tumor the size of a hazel nut, not definitely circumscribed. A second tumor was also observed in the neck. The capsule containing the radium bromid was protected from moisture by a rubber cot, and the patient applied it himself to the lesion on the mouth for fifteen to twenty minutes. The applications were made six times in less than a month. In seventeen days the tumor had perceptibly diminished in size and the ulcer began to heal over. No further visible reaction was observed at any time. The tumor rapidly subsided after this, and by the end of the month had apparently vanished. In the third case treated with the radium the same retrogression of the malignant tumor was realized.

102. **Radium Treatment of Cutaneous Affections.**—Holzknecht also exhibited at the same meeting several cases of cutaneous affections treated with the radium rays, one application each. One was a case of psoriasis gyrata of the entire body, which had been nearly cured with the *x*-rays and the cure was completed by the application of the radium. Very slight and brief application of the *x*-rays (2 H) are enough to cure psoriasis. The patches heal, while the sound skin is not affected by the applications. The same is true of the radium. A minute's application was amply sufficient. Recurrences will probably follow as after every method of treating psoriasis. In a case of lupus hypertrophicus one patch was cured with the *x*-rays and one with the radium. The latter was applied to the spot twice, at a month's interval, for seven minutes at a time.

The similarity of the action of the two kinds of rays was here striking, and the radium was superior, if anything, and can be applied to the mucous membranes. An epithelioma on the cheek also rapidly subsided till only a trace of infiltration around the edge still persists after three applications of the radium capsule for five minutes each. The most remarkable of all his cases was an extensive flat telangiectasia covering the entire left arm. He comments on the differences between the Becquerel and the Roentgen rays, laying special stress on the histologic studies of ray dermatitis which the Neisser school has published, Scholz's thesis in particular. The latter is a complete monograph on the histology of Roentgen dermatitis in man and animals. He has shown that the Roentgen rays cause degenerative processes in the cells of the intima of the blood vessels. The action of the radium rays seems to be identical, only much more intense. As a consequence of the degeneration there ensues a rapid dilation of the capillary and precapillary vessels. In the case of telangiectasia described, the radium capsule was applied for ten minutes each at eight various points on the nevus, while the parts between received only the small quantity of the rays that passed through the sides of the capsule. When exhibited, at these eight points there were corresponding small patches, .5 cm. in diameter, of perfectly normal, tender, white skin in the midst of the nevus vasculosus. Applications of the Roentgen rays had no such effect, but merely slightly blanched the points.

104. Blastomycosis.—Brandweiner exhibited at the same meeting a case of what he believed to be blastomycosis "in the sense of the Americans," and two others were reported by himself and Oppenheim. The latter stated that only 45 such cases have been published, and all but 2 in America, but he is convinced that many cases diagnosed as lupus verrucosus, epithelioma or syphilis must have been in reality cases of blastomycosis. Differentiation is important as potassium iodid is an energetic and certain specific against this affection.

107. Septicemia from Micrococcus Tetragonus.—Fornaca describes the case of a man of 45 who for three months exhibited chills and remittent fever of a pyemic type with much emaciation, a hemorrhagic pleural effusion and hypertrophy of the liver and spleen. Repeated exploratory puncture was negative, but a parasite supposed to be the white tetragonus was found constantly in the blood, in the pleural effusion and in the urine. The cultures on the most varied media were always white until the infection began to decline, when they became yellowish. The red corpuscles were somewhat altered, the hemoglobin low, and the whites numbered a third more than normal. The treatment instituted was endovenous injections of sublimate, and under their influence the proliferation of the bacteria in the blood was arrested, and they finally disappeared, while the blood rapidly regenerated, the number of whites subsided to normal, and the liver resumed its normal size. Before resorting to the sublimate, various other measures had been tried, but with no effect. The endovenous injections of 2 to 4 mg. of corrosive sublimate were repeated every day from April 22 to May 3, with marked influence on the temperature curve. The first four days there was a chill and fever to 40 and 40.5 C., but the temperature gradually subsided, and after the eleventh day there was almost complete apyrexia, but the symptoms still continued to simulate an abscess in the liver, to such an extent that the abdomen was opened and explored twice, but with negative results. After remaining in the neighborhood of normal for several days the temperature again rose and the sublimate injections were resumed and continued for nearly a month. They seemed to be perfectly tolerated and progressive improvement followed, the patient leaving the hospital, July 6, apparently cured. His first symptoms had been noted in December, and he entered the hospital in March.

110. Suprarenal Extract in Gastrointestinal Atony.—Baccarani reports from Galvagni's clinic at Modena very favorable results from the use of Vassale's extract of the medullary substance of the suprarenal capsules in 14 cases of atony of the stomach. Experimental and clinical tests demonstrated its marked influence on the motor function of the stomach, perceptible even from the outside. The effects in the clinic also suggested that the active principle secreted in the medullary substance of the suprarenal gland raises the tone of the cardiovascular apparatus and the metabolism in general. The benefits derived also suggest that certain cases of gastrointestinal atony with general asthenia, headache, insomnia, etc., may be due to simple functional insufficiency of the suprarenal capsules, transient or relative.

111. Hemostasis in Resection of Spleen.—Girolamo calls his method intralienal suture; it has been thoroughly tested on dogs. A silk suture is passed through the sound part of the spleen from within outward, about one centimeter below the free margin of the organ and eight millimeters from the line of the projected incision. Another needle on the same thread is then passed in the same way from the concave surface outward, about one centimeter beyond the first needle. A third and a fourth needle on the same thread are then inserted in the same way. The entire margin of the parenchyma of the spleen is thus included in the threads, which are tied in loops, after being cut at the eye of each needle. A single needle and several threads can be used instead of the single one if wished.

112. Paroxysmal Hemoglobinuria.—The authors suggest as a hypothesis from the findings in Case 1 that the hemoglobinuria was due to loss of balance between the resistance of the red corpuscles and the toxic action of the serum. The balance may be upset by cold, congestion, trauma or other cause. The resulting hemolysis is followed by a defensive reaction on the part of the organism and an antihemotoxin is elaborated which arrests the hemotoxic process. The red corpuscles are thereafter more resistant than normal, as was observed in the blood of this patient. There was no hemoglobinemia after the attack was once established. The other case was one of hemoglobinuria without hemoglobinemia. The serum had merely slight agglutinating power and the hemoglobinuria was probably to be ascribed to some morbid condition of the kidneys as symptoms of nephritis were noted.

115. Tonic Treatment of Epileptics.—Alessi calls attention to the great benefit he has derived in a number of cases of epilepsy from general tonic treatment. He has found very useful a combination of sodium arseniate 1 mg.; zinc phosphite 5 mg.; calcium phosphate 8 cg.; sodium benzoate and pancreatin, each 20 cg. Twenty such doses are given in all, one to three a day before meals. The zinc phosphite is both tonic and sedative. Sabbatani has established that lime reduces the excitability of the cortex, and the pancreatin has a favorable influence on

digestive processes. Alessi supplements it with a little rhubarb. In conclusion he reports four cases in detail treated on this principle, showing the improvement in cases in which the morbid process has not already induced irreparable anatomic changes. He emphasizes in conclusion that the physician should aim to cure the epileptic, not the epilepsy; the greater includes the less.

123. **Electric Wet Packs in Nervous and Mental Diseases.**—Rutkovsky has been advocating for some time local wet packs through which electricity is conducted, and now describes two cases in which the entire body was packed with these "electric compresses." Both were women, one a physician addicted to morphin, the other a case of neurasthenia, anemia, insomnia, etc. Marked benefit was derived in both. The patient is wrapped in a sheet wrung out of hot water, all but the head and one hand being thus covered. The cathode is applied to the feet and the anode, about 100 sq. cm. in size, is placed on the palm of the exposed hand. The current is turned on to the strength of 2 to 5 milliamperes for twenty to thirty minutes, reducing the strength whenever tingling is felt in the hand. The electric compress was applied twice at an interval of five days in the first case, and then several times later, and the patient said that she had never felt so well in her life; appetite and sleep have returned, and morphin has been abandoned. In the other case the neurasthenia inclined to melancholia with tendency to suicide, and the electric packs were supplemented by massage and suggestion. This treatment was successful after failure of all other measures during months of trial.

130. **Late Recurrences of Cancer.**—Heynatz has observed a number of cases in which cancer recurred after ablation more than three years previously. The late recurrences do not differ in any respect from those that appear in the first three years, and must be due to relics of the original tumor which have lain latent in the interim, even as long as twenty years in some instances. He, therefore, suggests that our acceptance of three years as the limit for a cure of cancer needs revision to conform to the clinical facts observed. In his own experience of 122 cases of recurrence, it was observed during the first year in 56; during the second in 46; during the third in 18, and after the third year in the same number. In one case, which he believes is unique, a recurrence the size of a pea was found in three months after ablation of a cancer on the tongue, but the patient has been in perfect health during the eight years since the recurrence was removed. The point which he wishes to specially emphasize is that recurrence at any date should be treated by prompt excision, and that the second operation may completely eradicate the malignant disease. His percentage of late recurrences is larger than those of Labhardt's statistics, and a much larger proportion were operable.

133. **Connection Between Affections of Female Genital Organs and the Nose.**—Liboff's experience confirms that of other authors who have reported great benefit in certain gynecologic affections from cocainization of the genital points in the nose. The results were surprisingly effective in nervous dysmenorrhea, that is cases in which nothing pathologic could be discovered in the genital organs to explain the painful menstruation. The measure is especially beneficial in the case of young girls or unmarried women, and cocainization of other points besides those described by Fliess as the genital points, may prove similarly effectual. The explanation of these results is probably that many gynecologic affections are traceable to some neurosis.

136. **Gastric Secretory Function, Especially in the Insane.**—There is a natural secretion of gastric juice as food is being taken and is passing through the natural passages, and this factor in digestion is lacking when the subject is being fed through a stomach tube. Consequently articles for this form of feeding should be selected with a view to compensate this lack. Yushtchenko has found that milk, as a natural stimulant for the nervous and glandular apparatus, is the best of all foods for artificial feeding, especially for patients with little if any appetite. He has also found that besides milk, bouillon and the meat powder sold in Russia, all act as stimulants for the secretory gastric functions, and are, therefore, best suited for gavage of the insane. They may be effectively supplemented by eggs and the bread powder which is another Russian article. The use of these stimulating foods supplies the nervous and glandular apparatus with the stimulus naturally afforded by exercise and appetite.

139. **Study of Alkalinity of Blood.**—In tests on dogs, rabbits and in the clinic, Orlovsky found that the degree of leucocytosis had no influence on the alkalinity of the blood, even when a hyperleucocytosis up to 75 per cent. existed. On the other hand, he is convinced that the alkalinity of the blood, that is, of its plasma, is an important factor in the biologic life of the organism, and that the degree of alkalinity is dependent on the number of red corpuscles, as the alkaline elements are contained in the latter as well as in the plasma. The fluctuations in the number of reds in various pathologic processes in the individual as also in the same process in different individuals, amply explain the variations in the alkalinity of the blood.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Microscopical Examination of Foods and Drugs. A Practical Introduction to the Methods Adopted in the Microscopical Examination of Foods and Drugs, in the Entire, Crushed and Powdered States. By Henry George Greenish, F.I.C., F.L.S., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain. With 168 Illustrations. Cloth. Pp. 316. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

Brewer's Surgery. A Text-Book of Surgery for Students and Practitioners. By George E. Brewer, A.M., M.D., Lecturer on Clinical Surgery at the College of Physicians and Surgeons (Medical Department of Columbia University), New York. With 280 Engravings and 7 Plates in Colors and Monochrome. Cloth. Pp. 712. Price, $4.00. Philadelphia and New York: Lea Brothers & Co. 1903.

Studies from Institute for Medical Research. An Inquiry Into the Etiology and Pathology of Beri-beri. By Hamilton Wright, M.D. (McGill), Director of the Institute for Medical Research, Federated Malay States. Printed by Authority of the Resident General, F.M.S. Vol. II, No. 1. Paper. Pp. 93. Price, 3s net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1902.

An English Handbook of the Paris Medical School. By A. A. Warden, M.D., Visiting Physician to the Hertford British

Hospital, Paris. With Prefatory Letters by Lord Lister and Prof. W. W. Keen. Paper. Pp. 72. Price, 2s. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

A COURSE OF LECTURES ON MEDICINE TO NURSES. By Herbert E. Cuff, M.D., F.R.C.S., Medical Superintendent Northeastern Fever Hospital, Tottenham, London. Fourth Edition. Cloth. Pp. 270. Price, $1.25 net. Philadelphia: P. Blakiston's Son & Co. 1903.

REPORT OF THE BUREAU OF VITAL STATISTICS of the State of New Jersey for the Year Ending Dec. 31, 1901. Pasteboard. Pp. 382. Trenton, N. J.: J. L. Murphy Publishing Company. 1903.

New Patents.

Patents of interest to physicians, granted July 7 and 14:

733120. Sanitary napkin holder. Frederick M. Baldwin, Winter Park, Fla.
733124. Hernial truss. Townsend Beckwith, Big Flats, N. Y.
733152. Empyema drainage device. Murdoch Chisholm, Halifax, Canada.
732732. Making lithophone and Glauber salt. William D. Gilman, Baltimore.
733026 and 733027. Inhaler. Sydney O. Goldan, New York.
732855. Pessary. Edgar M. Hewish, Philadelphia.
733049. Massage machine. Alva D. Jones, Louisville, Ky.
733228. Beverage dispenser. George A. Logan, Chicago.
732897. Apparatus for massaging. Graziano Sartori, Berlin, Germany.
732801. Machine for polishing atomizer tubes. Charles L. Turner, Winthrop, Mass.
732975 and 733358. Tachometer. Curtis H. Veeder, Hartford, Conn.
733364. Nebulizer. Robert L. Benson, Chicago.
733536. Case for clinical or other therometers. Frank J. Berberich, Jr., Brooklyn.
733899. Water bottle funnel neck. Robert D. Bradley, Canton, Ohio.
733472. Artificial limb. Erick H. Erickson, Minneapolis.
733398. Massage instrument. Benjamin E. Joseph, Chicago.
733402. Obstetrical forceps. Henry E. Koch, Hartington, Neb.
733729. Making cellulose esters. George W. Miles, Belmont, Mass.
733504. Medicated plaster. Frederic J. Nash, Brooklyn.
733879. Hernial truss. John B. Sheehan, Atchison, Kan.
733604. Apparatus for pasteurizing milk. Lee Sturges, Elmhurst, Ill.
733784. Massaging implement. Charles S. Whitney, Springfield, Ill.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended July 18:

Surgeon H. L. Law, retired, ordered to additional duty at Marine Recruiting Station, Providence, R. I.

Asst.-Surgeon H. L. Brown, appointed asst.-surgeon, with rank of lieutenant, junior grade, from June 29, 1903.

Asst.-Surgeon J. C. Thompson, detached from the *Columbia* and ordered home to wait orders.

Asst.-Surgeon C. H. DeLancy, detached from the Navy Yard, Norfolk, Va., and ordered to the *Columbia*.

A. A. Surgeon G. R. Plummer, ordered to Naval Station, Key West, Fla.

Surgeon C. H. T. Lowndes, detached from the Naval Station, San Juan, P. R., and ordered home to wait orders.

Surgeon G. Pickrell, ordered to Naval Station, San Juan, Porto Rico.

Surgeon H. N. T. Harris, orders of July 8 modified; detached from *Glacier* and ordered to Navy Yard, Pensacola, Fla.

P. A. Surgeon W. H. Bucher, detached from Navy Yard, Pensacola, Fla., and ordered to Washington, D. C., July 21, for examination for promotion, and thence to San Francisco to take passage on S. S. *Siberia*, sailing August 8 for Asiatic Station, for duty at Navy Yard, Cavite, P. I.

Asst.-Surgeon J. C. Thompson, orders of July 14 modified; detached from *Columbia* and ordered to *Chesapeake*.

Asst.-Surgeon A. J. Geiger, detached from Naval Hospital, Navy Yard, Norfolk, Va., and ordered to Washington, D. C., for duty as recorder of naval and medical examining board now in session at Naval Museum of Hygiene and Medical School.

A. A. Surgeon R. B. Chapman, ordered to duty with Recruiting Party No. 6.

A. A. Surgeon L. H. Schwerin, detached from duty with Recruiting Party No. 6 and ordered to the *Southery*.

A. A. Surgeon F. W. Tyree, ordered to the Naval Station, Port Royal, S. C.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended July 16, 1903:

P. A. Surgeon J. C. Perry, granted leave of absence for one month from July 14.

P. A. Surgeon M. J. Rosenau, to proceed to Boston, Philadelphia, Marietta and Swiftwater, Pa.; Detroit, St. Louis, Milwaukee, Wis.; Chicago and Baltimore for special temporary duty.

P. A. Surgeon H. W. Wickes, granted leave of absence for one day, July 17.

P. A. Surgeon T. Clark, granted leave of absence for seven days from July 13, 1903, under paragraph 191 of the Regulations.

Asst.-Surgeon T. B. McClintic, to proceed to Atlantic City, Point Pleasant and Tuckerton, N. J., for the purpose of making physical examinations of keepers and surfmen of the Life-Saving Service.

Asst.-Surgeon F. E. Trotter, granted seven days' extension of leave of absence from July 13.

Asst.-Surgeon C. W. Wille, to proceed to Ocean City, Md.; Chincoteague Island and Onley, Va., to make physical examinations of keepers and surfmen of the Life-Saving Service.

A. A. Surgeon P. N. Barnesby, granted leave of absence for two weeks, on account of sickness, from July 2.

A. A. Surgeon W. R. Hicks, granted leave of absence for three days from July 14.

A. A. Surgeon C. B. Sweeting, granted leave of absence for thirty days, on account of sickness, from July 10.

A. A. Surgeon Jay Tuttle, department letter granting leave of absence for thirty days amended so as to be effective July 3.

A. A. Surgeon W. A. Weldon, granted leave of absence for fifteen days from July 11.

BOARDS CONVENED.

Board convened at the Marine Hospital, Port Townsend, Wash., July 17, 1903, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon J. H. Oakley, chairman; P. A. Surgeon M. H. Foster, recorder.

Board convened at the Marine Hospital, Chelsea, Mass., July 21, 1903, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended July 18, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, July 4-11, 2 cases.
California: San Francisco, June 28-July 5, 3 cases.
Georgia: Atlanta, July 1-8, 1 case.
Illinois: Chicago, July 4-11, 4 cases.
Indiana: Kokomo, July 4-11, 2 cases.
Louisiana: New Orleans, July 4-11, 2 cases.
Maine: Fort Kent and vicinity, July 10-14, 24 cases.
Massachusetts: Fall River, July 4-11, 15 cases; New Bedford, July 4-11, 2 cases; Taunton, July 4-11, 2 cases.
Michigan: Detroit, July 4-11, 11 cases; Port Huron, July 4-11, 3 cases.
New Jersey: Camden, July 4-11, 1 case.
New Hampshire: Manchester, July 4-11, 3 cases.
New York: New York, July 4-11, 1 case.
Ohio: Cincinnati, July 3-10, 2 cases; Cleveland, July 4-11, 1 case; East Liverpool, June 1-30, 6 cases; Hamilton, July 4-11, 4 cases, 2 deaths; Toledo, July 4-11, 2 cases.
Pennsylvania: McKeesport, July 4-11, 1 death; Philadelphia, July 4-11, 54 cases, 11 deaths; Pittsburg, July 4-11, 47 cases, 2 deaths.
South Carolina: Charleston, July 4-11, 4 cases.
Tennessee: Memphis, July 4-11, 2 cases; Nashville, July 4-11, 3 cases.
Utah: Salt Lake City, June 27-July 11, 8 cases, 1 case imported.
Wisconsin: Milwaukee, June 27-July 4, 6 cases.

SMALLPOX—FOREIGN.

Austria: Prague, June 13-20, 6 cases.
Belgium: Brussels, June 20-27, 5 deaths.
Brazil: Pernambuco, May 8-31, 11 cases.
Canary Islands: Las Palmas, June 13-27, 10 cases.
Colombia: Bocas del Toro, June 23-30, 8 cases, 1 death.
Ecuador: Guayaquil, June 20-27, 1 death.
France: Marseilles, May 1-June 30, 19 cases, 32 deaths; Rouen, May 1-31, 3 deaths.
Great Britain: Birmingham, June 20-27, 4 cases; Dublin, June 20-27, 9 cases, 2 deaths; Dundee, June 13-20, 2 cases; Leeds, June 27-July 4, 4 cases; Liverpool, to July 4, 28 cases, 4 deaths; Manchester, June 20-27, 10 cases; Newcastle-on-Tyne, June 13-27, 9 cases; Nottingham, June 20-27, 4 cases; Sheffield, June 13-20, 1 case; Southampton, June 13-20, 1 case from S. S. *Paul*, from New York.
India: Bombay, June 9-16, 27 deaths; Calcutta, June 6-13, 2 deaths.
Mexico: City of Mexico, June 14-27, 29 cases, 20 deaths.
Russia: St. Petersburg, June 20-27, 11 cases, 3 deaths; Warsaw, June 6-13, 2 cases.
Spain: Barcelona, June 13-20, 7 deaths.
Turkey: Constantinople, June 21-28, 1 death.

YELLOW FEVER.

Colombia: Panama, June 20-July 6, 6 cases, 2 deaths.
Costa Rica: Limon, June 24-July 2, 7 cases, 1 death.
Cuba: Havana, July 14, 1 death, patient taken from S. S. *Vigilancia* from Progreso.
Mexico: Progreso, June 21-July 5, 2 cases; Tampico, June 27-July 4, 28 cases.

PLAGUE—INSULAR.

Hawaii: Honolulu, July 3, 1 death.

PLAGUE—FOREIGN.

Australia: Queensland, Brisbane, May 9-30, 2 cases, 2 deaths; Bundaberg, May 16-23, 1 case, 1 death.
Western Australia: Freemantle, June 10, 1 case.
Egypt: Alexandria, June 6-13, 4 cases, 2 deaths; Beni Mazar, June 6-13, 2 cases; Port Said, June 6-13, 1 case, 1 death; Tukh, June 6-13, 8 cases, 2 deaths; Samalut, June 6-13, 2 cases, 2 deaths.
India: Bombay, June 9-16, 186 deaths; Calcutta, June 6-13, 15 deaths; Karachi, June 7-14, 15 cases, 13 deaths; Mauritius, June 4-11, 2 deaths.
Japan: Nagasaki, May 27, 1 death; Yokohama, June 6-13, 3 cases, 2 deaths.

CHOLERA.

India: Calcutta, June 9-16, 45 deaths; Madras, June 6-12, 1 case, 1 death.
Straits Settlements: Singapore, May 16-30, 20 deaths.

Address.

THE ESSENTIAL PRINCIPLES OF INFANT FEEDING AND THE MODERN METHODS OF APPLYING THEM.*

THOMAS MORGAN ROTCH, A.B., M.D.
Professor of Pediatrics, Harvard University.
BOSTON.

The question of infant feeding is a very broad one; too broad, in fact, to be covered in one evening, or in one address.

Although we usually consider that human beings are infants during the first two years of life, yet, so far as their feeding is concerned, it is the first twelve months of their existence in which the greatest difficulties arise in the proper adaptation of their food to their individual digestion, and to the requirements of their individual nutrition.

An address on infant feeding, therefore, should naturally be devoted to the feeding of the first twelve months of life. It has for many years been an accepted fact the world over that the mortality of infants who are fed on good human milk, obtained from their mothers or other healthy women, is lower than that achieved by any other method of feeding. It should, however, at once be insisted on that experience has also shown that it is good human breast milk, and good according to the modern sense of the word, which has produced these results. Poor milk from human beings, poor because they contain inadequate percentages of the various elements of the milk, such as the fat, sugar and proteids, or because of the improper combination of these elements, can, as it has often been proved, produce diseases, especially those which are connected closely with nutrition. The most common of these diseases are rhachitis, infantile atrophy, infantile scorbutus and the various gastro-enteric disturbances, which not only lead to malnutrition, but also render the infant vulnerable to specific diseases caused by specific organisms.

Since there are many causes and reasons through which the human infant may at any time, and in any place, be deprived of its natural food obtained from the human breast, it is evident that some other food must be substituted in order that the infant should live. It is well, therefore, when any food is to be substituted, excepting that which Nature has provided in the human breast, that we should speak of it as a substitute food. We should, however, admit that the great majority of cases of substitute feeding merely represents failures of breast feeding either because the mother will not or can not nurse her infant. Whatever the cause, the great majority of these failures of breast feeding could have been avoided and the infant fed on a substitute food successfully if the modern methods, representing the principles of percentage feeding, could have been early instituted and intelligently followed.

The substitute feeding of infants is not one of choice, but of necessity. The question, then, which must continually arise is: What materials and what methods have been found by the latest practical and scientific investigations to be best adapted to the infant when good breast milk can not be obtained?

Allowing that good human breast milk is the best food for infants in the first year of life, what I am about to say is directed to the subject of substitute feeding, a subject which must be met and dealt with as any other life-saving question.

In studying the methods of human breast feeding and the materials of which the human breast milk is composed, we have arrived at the following conclusions, which should be distinctly and concisely stated before taking up the question of the methods and materials for substitute feeding.

HUMAN BREAST MILK.

Human breast milk is practically sterile as it enters the infant's mouth, and is obtained by suction; it is either amphoteric or slightly alkaline in its reaction; it has a temperature of about 98 to 100 F. (36.7-37.7 C.) when it enters the infant's mouth. While it is recognized that various salts are present in solution in human milk, our modern investigations have not yet been carried so far as to obtain any practical clinical advantage in attempting to deal precisely with these salts when the milk of another mammal is used as a substitute for human milk. The three broad representatives of foodstuffs, the fats, the sugar and the proteids which occur in human milk, are the ones which we must practically deal with in making a substitute food. These three essential elements, forming the material to be used for the nutrition of the infant, do not always occur in the same percentages in the product of the mammary gland of healthy women. We must, therefore, accept the fact, which has now been established by the best chemists all over the world, that human breast milk is a food varying in its percentages, but that normally its percentages usually appear to be within certain limits. Thus, the food may safely vary from 3 to 4 per cent. in fat; the sugar, which is less varying than any of the other constituents of milk, may vary from 6 to 7 per cent., and the proteids from 1 to 2 per cent. This, however, does not mean that a somewhat higher percentage of fat than 4 must necessarily be unfit for the infant, nor that a decidedly higher percentage of the proteids than 2 must necessarily be undigestible, nor that the infant can not thrive on less

* An address delivered by request of the Ohio State Pediatric Society at Dayton, Ohio.

than 3 per cent. of fat, or 6 per cent. of sugar. It does, however, show that human milk is a varying quantity, and that it is, therefore, not adapted to the digestion and nutrition of all infants, but that, on the contrary, a given percentage and combination of percentages may or may not be suited to the individual digestion and absorption of the infant. This explains why when one infant may be thriving on the milk of a healthy woman, this same milk from the same source may cause serious digestive disturbances in another infant.

It is very evident that the successful feeding of infants, whether it be by means of human or substitute food, is essentially an adaption of special percentages of the different elements of the milk, and of special combinations of these percentages to the individual infant. We should also always bear in mind that in addition to the composition of the milk equal attention should be paid to the temperature, to the sterility of the food, to its freshness, and to the quantity at each feeding, adapted, according to the age and weight of the infant, to the size of its stomach. The question of the capacity of the infant's stomach must especially be taken into consideration, for experience has shown that, while it is very seldom that disturbances of digestion and nutrition arise from the infant being allowed to take as much of the milk from the human breast as it wishes, this same infant will take more from a bottle than its stomach can accommodate. In this way it may suffer from mechanical dilatation of the stomach, and from lessening of the elasticity of its walls, with a resulting interference with its functions.

The following table represents analyses of good human breast milk, made by our most competent chemist, Dr. Charles Harrington, of Harvard University. The table shows the varying percentages and combination of percentages which may arise in the milk of equally healthy women whose infants were thriving. They were all cases which occurred in my practice, and were, therefore, under my own observation.

TABLE ONE—HUMAN BREAST MILK ANALYSES (HARRINGTON).[1]

Fat.—In regard to the composition of milk, it will be well to speak first of the quality of the fats which occur in the human milk. This fat consists chiefly of palmatin, stearin and olein, only about 2 per cent. of the total fat consisting of the glycerides of butyric, caproic, caprylic and myristic acids. The production of animal heat is so very important a part of the infant's well-being that it is not surprising that we should find so large a percentage of fat as 4 per cent. in the food which is provided for it, and it is very evident that this fat is put there not only for the purpose of nutrition, but also as a means of maintaining bodily heat. This latter function of the food can not with impunity be trifled with, for it is essential for the active metabolism, the importance of which we are forced to recognize when we are attempting to provide a substitute food. A proper amount of fat is also probably of great aid in the regulation of the fecal discharges, and for this purpose probably varies in the individual infant according to its individual idiosyncrasies. It is presumable also that the percentage of fat in the individual cases should be proportionate to the proteids, and this proportion is of great aid in the proper digestion of the proteids. We should, therefore, naturally expect that unless the standard percentage of fat, or at least a near approach to it, is present in the mother's milk, trouble will be likely to arise with her infant, and this has been my experience. I have found clinically that with the fat much lessened the nutrition suffered, the digestion was not good, and that there was a tendency to constipation, while when its percentage was decidedly above the standard the digestion was weak, there was a tendency to diarrhea, and in consequence a disturbance of nutrition.

These clinical observations at once suggest that in the management of infant feeding we must recognize the existence of two important conditions. One of these is the digestion of the infant, and the other is its nutrition. These two requirements are essential for a successful lactation. Milk may be easily digested but not nutritious, and it may be highly nutritious but difficult to digest, so that it is the equilibrium of these two conditions which produces a perfect infantile development. Although it is admitted that a large percentage of surplus fat is frequently found in the feces of infants whose digestion and nutrition are normal, and whose food is human milk, yet we have no more right to conclude from this that a smaller percentage of fat is sufficient for nutrition, or that a surplus eliminated by the feces is unnecessary, than we have to assume that there is too much oxygen in the blood because we find a certain surplus of oxygen in arterial blood which is returned to the lungs in the pulmonary veins. In fact, it is far more probable that Nature introduces a certain percentage of fat in human milk with a purpose which can be accomplished only by that percentage, so that it is an error to change this percentage beyond the variation which commonly occurs in average human milk, unless we find from direct clinical evidence in the special case that such a variation is demanded. There are, for example, many cases, especially in premature babies, and in babies with especially weak fat digestions in which greater variations than normally occur in human milk are called for, and for whom very low percentages of fat may be necessary.

Sugar.—The form of sugar which is found in human milk is called milk sugar, or lactose. It is more digestible than fat, but does not have so much potential energy, that is, so much heat-producing power in a given weight. The potential energy of the fat is to that of the sugar as 2.4 to 1. The conversion of sugar into lactic acid gives rise to many of the changes occurring in milk; for instance, the fermentation of the lactose with the production of lactic acid and the subsequent coagulation of the caseinogen by the lactic acid is one of the most common changes which milk undergoes. This process is the ordinary souring of milk. It is due to Hueppe's

	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00

1. Mothers healthy, and infants all digesting well and gaining in weight.

"bacillus of lactic acid," which seems always to be present. Over one hundred other kinds of bacteria appear to have this same property. The *Bacillus lactis aerogenes,* described by Escherich, is closely allied to Hueppe's bacillus, and also to the *Bacillus coli communis,* which has the same property of producing lactic acid fermentation. These bacilli are easily killed at a low temperature, and their growth is checked when lactic acid has been formed to the extent of 1 per cent. The formation of lactic acid by the *Bacillus lactis aerogenes* prevents fermentation in the stomach and intestines. The *Bacillus lactis aerogenes* is present in normal digestion, and acts on the milk sugar to produce an organic acid which drives out the more noxious forms of bacteria which by their presence interfere with normal digestion. This may be given as one of the chief among the many reasons why milk sugar should be used in milk modifications, instead of cane sugar, when we are preparing a substitute food.

Proteids.—The nitrogenous constituents of milk consist of two distinct elements, caseinogen and the proteids of whey; the latter consist chiefly of lactalbumin and lactoglobulin, and of these the former is greatly in excess. It has been found more convenient and practical to use the word whey-proteids as a general name to include lactalbumin, lactoglobulin and the nitrogenous extractives of whey. The caseinogen and whey-proteids make up approximately the total per cent. of the nitrogenous matter in both human and cow's milk, but their relative proportions to each other varies greatly in the two milks. Thus, according to König, as shown in Table 2, the caseinogen in human milk is represented by 0.59 per cent., while in cow's milk it is represented by 2.88 per cent.; the whey-proteids in human milk are 1.23, while in cow's milk they are only 0.53 per cent. Although these figures are not accepted by all chemists, there is undoubtedly a much greater proportion of the whey-proteids in human than in cow's milk, and a much greater proportion of caseinogen in cow's milk than in human milk.

Table 2.

	Woman's Milk.	Cow's Milk.
Caseinogen	0.59	2.88
Whey proteids	1.25	0.53
	1.82	3.41

Caseinogen is the part of milk which gives rise to curds; it is precipitated by acids by the rennin ferment, and by gastric juice. It is the most indigestible part of milk, and unquestionably its very large proportion in cow's milk is one of the principal reasons why cow's milk has given so much trouble in infant feeding, as compared with human milk. Whey, on the other hand, is the most digestible part of cow's milk, and its proteids remain in solution, and are not precipitated by either acids or rennin or gastric juice, but are readily converted into the albumoses and peptones, and so are easily absorbed. The whey-proteids are partially coagulable by temperatures above 161 F. (72 C.).

There is much about the proteids of milk which is still undetermined, but it is important to recognize these differences in the relative proportions of caseinogen and whey-proteids, and in their chemical properties, for we may now so modify cow's milk that by using whey as a diluent in place of water, we can make the whey-proteid element relatively greater than the caseinogen, and by so doing approach more closely the composition of human milk.

Assuming the necessity of a substitute feeding, we must first make a choice of the best materials to use in the making of a substitute food. If again the product of the human mammary gland in its composition is taken as a standard for a substitute food for the human infant, we must at once acknowledge that the milk of no other mammal approaches the human sufficiently close to permit of its being given in a purely undiluted form.

Comparative analyses of mammal's milk.

The following figures, which show the comparative analyses of the milk of the goat, ass and cow, animals whose milk is most readily obtained for an infant's food all over the world, illustrate this statement.

Table 3.

Comparative analyses of goat's, ass' and cow's milk.

	Fat.	Sugar.	Proteids.	Mineral Matter.	Total Solids.
Goat (low in sugar and high in proteids)	4.3	4.0	4.6	0.6	13.5
Ass (low in fat)	1.6	6.1	2.2	0.5	10.4
Cow (low in sugar and high in proteids)	4.00	4.50	3.5	0.7	13.0

It is self-evident that if any of these milks are to be adapted to our standard they must be in some way modified, that is, their three principal constituents, the fat, the milk-sugar and the proteids must be changed in order to make them at all similar to the percentage composition of human milk.

It is important to remember that the simple dilution of milk with water, or the addition of lime-water or of sugar, is in fact a modification of milk. Modification of milk, therefore, in a substitute infant food is a *sine qua non,* and must be done in all cases except in those very rare exceptions in which the infant is able to digest undiluted milk.

As one milk has to be modified as well as another, and as none of the milks of the animals which I have just enumerated contains any inherent quality which would lead to its being used without some form of modification, physicians have found it most convenient to use the milk of the cow, and it is the milk of the cow which I shall consider to-night in speaking of the modification of milk. The important question in discussion should be, then, how far shall the modification of milk be carried out, and how scientifically and accurately can it be done?

Breeds of cows.

Supposing that the cow is the animal from which we decide to feed the infant, a few words concerning the cow will be practical at this part of the discussion. It has been found that the percentages of the fat, sugar and proteids vary in the different breeds of cows. It is, therefore, necessary to know which breed of cows provide the most stable percentages in its milk, and is therefore the one best adapted for infant feeding. The higher grades of cattle have been found not to give the best milk for a substitute feeding. The fat in the milk of the cows originating from the Channel Islands, that is, the Jerseys and Guernseys, differs considerably from that of other breeds, and also from that of human milk, and it has been found from long clinical experience that the milk of these breeds is much less digestible than that from less highly bred cows, such as the Holstein and Ayrshire.

The breed of cow should then be chosen according to the quarter of the world in which we are feeding the infant, and, in making this choice, we should recognize that the percentages of the elements of the milk are not the same, not only in the different breeds, but in different herds of the same breed, and we should, in attempting

to obtain precise percentages from these milks, understand that these differences exist, and that they must be taken into account in our calculations. It is also a fact that there is a marked difference in cow's milk at different seasons.

The following Table 4 shows the analyses of the milks of different breeds of cows:

TABLE 4.

	Durham or Shorthorn.	Devon.	Ayrshire.	Holstein.	Brown Swiss.	Jersey.	Common Native.	American Grade.
Fats	4.04	4.09	3.89	2.88	4.00	5.21	3.69	4.01
Sugar	4.34	4.32	4.41	4.33	4.30	4.52	4.35	4.36
Proteids	4.17	4.04	4.01	3.99	4.00	3.99	4.09	4.06
Mineral matter	0.73	0.76	0.73	0.74	0.76	0.71	0.73	0.74
Total solids	13.28	13.21	13.04	11.94	13.06	14.43	12.86	13.17
Water	86.72	86.79	86.96	88.06	86.94	85.57	84.14	86.83
	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00
Daily quantity	large	moderately large		very large	mod. large	mod. small	large	mod. large

It is to be noted that the percentage of fat in the herds of Holsteins on the Walker-Gordon farms average from 3 to 4 per cent., as contradistinguished from the average Holstein of 2.88, as shown in the table.

In comparing Jersey milk with other milks we find that human milk contains only a small proportion of the glycerids of the fatty acids, such as butyric, caproic and caprylic; also that the milk of the Holstein has a much larger proportion of the stable fats, such as olein, stearin and margarin, than does that of the Jersey, which contains a much larger proportion of volatile glycerids. These volatile glycerids do not exist in the mammæ, but are formed in the milk soon after milking, and this change takes place more quickly in some breeds than in others, and notably so in the milk of the Jerseys and Guernseys. In the emulsion of milk from Jersey cows the corpuscles are much larger than in the Holstein, while the Holstein emulsion when broken down is much more easily restored, that is, it emulsifies better and resists better a destruction of its emulsion, such as occurs when cream is produced, than do the milk of the Jerseys and Guernseys. The emulsion of the fat in the milk of the latter breeds is easily broken up, is more apt to produce oil drops on the top of the bottle, and when disturbed is not so easily restored. This latter fact is one of considerable importance when we are dealing with the rather difficult question of transporting modified milk.

ACTION OF HEAT.

A few words as to the action of heat on milk and its modifications will be of practical value to the physician when in writing a prescription for a food he has to determine either the degree of heat needed for the special transportation or for the gastro-enteric disturbance with which he is dealing: 1. Most pathogenic organisms are destroyed at from 140 F. (60 C.) to 147 F. (64 C.). 2. Certain spores are not destroyed by a single pasteurization. 3. All spores are destroyed in a heat of 248 F. (120 C.). 4. All germs are destroyed at 154 F. (68 C.). 5. The tubercle bacillus has lived in a heat of 149 F. (65 C.) with one hour's exposure. 6. Lactalbumin, the principal of the whey-proteids, begins to coagulate at 158 F. (70 C.). 7. The rennin enzyme is destroyed at 140 F. (60 C.). (The last two points are of practical importance when whey is used in a modification of milk.) 8. A temperature of 155 F. (68 C.) is the temperature now used for pasteurization, as it is sufficiently high to kill practically all pathogenic germs found in milk, without coagulating the lactalbumin, or producing any change which can be detected by taste or by the appearance of the milk. 9. If a modified milk which contains a high percentage of sugar and of lime-water higher than 10 per cent. is heated as high as 212 F. (100 C.) and sometimes even at lower temperatures, the mixture becomes brown, seemingly from the combined action of the heat, the milk-sugar, and the lime-water producing a caramel.

When milk is heated to 158 F. (70 C.) a certain amount of the lactalbumin and lactoglobulin is coagulated, but the major part of the lactalbumin is converted into a form which is precipitated by acids, magnesium sulphate, and by other precipitants of casein which do not act upon the lactalbumin in its natural state. At 177 F. (80 C.) certain organized principles undergo a change, the nature of which is not known, but the evidence of which is found in certain chemical reactions. At 212 F. (100 C.) calcium citrate is deposited, some oxidation of the sugar occurs, and a deposition of certain salts and albumin on the fat globules occurs, causing the latter to rise and coalesce. At temperatures exceeding 140 F. (60 C.) a skin is formed if the milk is exposed to the air, consisting probably of an oxidized product of casein, together with calcium salts and some fat. When heated above 158 F. (70 C.) the taste and smell of milk are altered.

COMPOSITIONS OF MILKS.

It will now be easily understood why if a modification of milk for a substitute feeding is necessary, it should be accurate, must be expressed in the percentages of the constituents of the milk, namely, the fat, sugar and proteids, and that the alkalinity and the temperature should be stated. In order to accomplish this, the matter is greatly simplified by thinking and speaking in percentages, and in order to obtain definite percentages we must, of course, know the composition of the materials used, and we must also devise methods by which we can calculate how much of these different materials must be used in order to get the different percentage combinations of the fat, sugar and proteids. The following table compares the elements of human and of cow's milk:

TABLE 5.

	Human Milk.	Cow's Milk.
Reaction	Slightly alkaline.	Slightly acid.
Specific gravities	1028 to 1034	1032
Water	87 to 88 per cent.	86 to87 per cent.
Total solids	12 to 13	13 to 14
Fat	3 to 4	4.00
Milk sugar	6 to 7	4.50
Total proteids	1 to 2	3 50
Whey proteids	1.23	0 53
Caseinogen	0 59	2.88
Mineral matter	0.1 to 0.2	0.70

It can be easily seen by referring to the above table that simple dilution with water will not make cow's milk similar to human milk, for, although we may by such dilution reduce the proteids to the same percentage which occurs in human milk, yet at the same time we have so reduced the fat and the sugar that the food would in few cases prove to be nutritious. Moreover, if the total proteids in cow's milk are reduced by means of dilution until we obtain a proper percentage of caseinogen by so doing

the whey-proteids will be diminished far below their relative proportion in human milk, since by referring to Table 5 it will be seen that the whey-proteids in cow's milk are already in much smaller proportion to the caseinogen than they are in human milk.

COMPOSITIONS OF CREAMS.

In like manner if we dilute different creams we shall find that the same objections hold for them as for the simple dilution of milk. For instance, an analysis of a 16 per cent. cream shows fat 16 per cent., sugar 4.05 per cent., proteid 3.20 per cent. In this case simple dilution with water sufficient to reduce the fat to 4 per cent. would reduce the sugar to 1.01 per cent., and the proteids to 0.80 per cent. It is therefore evident that still further modification must be carried out in order to raise the sugar and proteid percentages to make them equivalent to those of human milk.

It will now be understood that in order to obtain mixtures containing varying percentages of fat, sugar and proteids we shall have not only to dilute cream in order to obtain our fat percentage, but must add milk-sugar, either in a solution of definite percentage or in a dry form, in order to raise the sugar percentage, and some material such as fat-free milk, by which we can obtain the desired percentage of proteids.

Cream is evidently the most natural and practical material to use. It is also evident that the cream must have a definite percentage of fat in order that we should be able to calculate and obtain the percentage of fat desired in the mixture. Moreover, we must make use of creams of different strengths in order to make it possible to obtain certain combinations of proteids with a given percentage of fat.

The following Table 6 will illustrate the limitations in the percentage of proteids dependent on the use of creams of different strengths:

TABLE 6.

	Per cent. Fat.	Lowest possible proteids of.
10 per cent. cream gives with	1	0.38
10 per cent. cream gives with	2	0.67
10 per cent. cream gives with	3	1.00
10 per cent. cream gives with	4	1.34
12 per cent. cream gives with	1	0.27
12 per cent. cream gives with	2	0.54
12 per cent. cream gives with	3	0.82
12 per cent. cream gives with	4	1.08
16 per cent. cream gives with	1	0.20
16 per cent. cream gives with	2	0.40
16 per cent. cream gives with	3	0.60
16 per cent. cream gives with	4	0.80
20 per cent. cream gives with	1	0.15
20 per cent. cream gives with	2	0.31
20 per cent. cream gives with	3	0.46
20 per cent. cream gives with	4	0.62

You will thus appreciate that unless the physician knows not only the percentage of the fat in the cream which he uses, but also what limits of proteids he can obtain by the use of such a cream, he can not prescribe exactly the proteid percentage. He also must realize the risk which arises from not knowing whether he is dealing with an infant who may or may not be especially susceptible to variations in the percentages and combinations of the fat and the proteids in its food. Just as an exact and proper modification of milk may accomplish very favorable results, so an improper modification of milk may be unsafe for the patient, and in fact may lead to symptoms worse than indigestion, such as infantile atrophy, rhachitis and scorbutus.

VARIATIONS OF DIGESTION.

There is not much question, from my somewhat extended experience in the feeding of infants whose digestions are normal and also of those in whom it is abnormal, that infants show pronounced variations in their function of digestion. Although a number of normal infants may readily digest a combination of percentages which corresponds to the composition of average human milk, yet there is no doubt that many normal infants show decided idiosyncrasies of digestion, and that we, therefore, can not be satisfied in giving such infants a milk which simply duplicates the percentages of average human milk. We must, on the contrary, be prepared at any time to meet such idiosyncrasies, and when we take into consideration the variations in digestion which must necessarily occur under conditions corresponding to varied ages and abnormal digestions, there is no doubt logically but that methods for obtaining a great variety of percentages and combinations of percentages are essential for the successful feeding of large numbers of infants.

An instance which has come under my notice illustrates what I have just said. Let us suppose that you are called on to prepare a substitute food for a premature infant whose function of digestion is very weak and undeveloped. If to such an infant a substitute food corresponding in its percentage combination to good average human milk, that is, fat 4 per cent., sugar 7 per cent., proteid 1.40 per cent., is given (as happened in one case which I have recently seen), disastrous results might occur, and it did in the case just referred to. Convulsions and symptoms of serious indigestion appeared and the infant died. If, on the other hand, this infant had been fed with an accurately prepared food of fat 1.50 per cent., sugar 4 per cent., total proteid .50 per cent., or preferably by a split proteid calling for caseinogen 0.25 and whey-proteid 0.25 it might have lived. It has also been pretty well proved that infants throughout the early months of life, and often during the first year, seem to have an idiosyncrasy which either allows them to digest or prevents them from digesting a low or high percentage of one of the elements of milk as well as of two or three. While certain infants may digest and thrive on the average percentage of sugar and proteids, they may be unable to digest even a very low percentage of fat. In like manner they may have a weak sugar digestion, and, as is so often found, a weak proteid digestion. It has also seemed to me in my studies that certain infants have an idiosyncrasy which prevents them from digesting the average percentage of caseinogen; and in some cases we shall probably find that a similar idiosyncrasy exists in reference to the ability of an infant to digest the percentage of whey-proteids which would be easily tolerated by an average normal infant.

PATENT AND PROPRIETARY FOODS.

A word here will probably be useful in regard to the patent and proprietary foods. They are all pretty much of one class, and in most cases contain a considerable amount of starch. The analyses of these foods show that without exception some of the principal three elements, especially the fat or proteids, are so low in their percentages that they must be modified in order to be nutritious. Without the addition of milk in some form they are undoubtedly not nutritious, and are practically useless. If, on the other hand, milk be added to them in order to make them nutritious, the question at once becomes one of the modification of milk, and in that case it is much more simple at once to modify good pure cow's milk. These foods, however, do much more harm than that which is connected with their lack of nutritious ele-

ments. One point is that they almost always contain some element which is not in human milk, such as starch, which in very young babies may seriously disturb digestion. Another harm that I refer to is that they encourage carelessness of the selection of the milk supply which is used in connection with them, in that the parents are led to believe that the chief virtue of the food lies in the food itself, and not in the milk which is added to it. Mothers and nurses are therefore very apt to use a poor milk supply, and are indifferent to the fundamental principles of scientific feeding, since they believe that the important point is the selection of some particular brand of patent or proprietary food. It would be just as sensible to attribute the entire success of an infant that is thriving on a substitute food to the milk-sugar which happens to be used in an ordinary modification.

If the physician wishes, for a definite purpose, or as he naturally would, during the tenth, eleventh and twelfth months of life to use starch in his substitute food, the starch should be presented in definite percentages. Thus cereal solutions can be added in place of the boiled water in any combination without altering the percentage of fats and proteids, and the percentage of starch thus added may be accurately determined if the percentage strength of the cereal solution is known. For instance, if fourteen ounces of a 1 per cent. solution of barley water is added in place of the boiled water, to a twenty-ounce mixture, the percentage of starch in the mixture is:

$$\frac{14 \times 1}{20} \text{ or } 0.70 \text{ starch.}$$

It is well here to state my views concerning the use of starch in any form in the early weeks and months of life. The amylolytic function of the infant is but very little developed at birth. It gradually increases as the infant grows older and has attained the stage of development by the tenth, eleventh or twelfth month which warrants its being used at that time for the conversion of starch into sugar. If it is used in the early months of life, we are taxing an undeveloped function, and we are liable to have results as deleterious to the infant's welfare as we should were we to tax the function of walking and standing at too early a period. It is quite as illogical and detrimental to the infant's welfare to tax an undeveloped function as it is not to make use of such function when the time for using it has arrived. Thus we should make use of the amylolytic function in the latter part of the first year, since at that time it is ready for use, just as we allow the child to stand at the same period.

The advantage which used to be claimed for the use of starch in a substitute infant's food was that it broke up the caseinogen in the milk, and thus made a finer coagulum, and one more similar to that which occurs in human milk. This action of the starch on the coagulum is, however, required in comparatively few cases, as we have learned to deal with the coagulum in a different way since we have instituted a method by which the caseinogen which forms the coagulum can be reduced to a very small percentage, while the whey-proteids, which are almost as nutritious as the caseinogen, can be used in quite a large percentage. By this method we can obtain a toal proteid percentage as high as 1.15 per cent., of which 0.90 per cent. is whey-proteids, and 0.25 per cent. is caseinogen.

The following Table 7 shows the combinations possible in these whey-cream mixtures, when prescribing from the milk laboratories:

TABLE 7.

Whey proteids, per cent.	Caseinogen, per cent.
0.25	0.25
0.50	0.25
0.75	0.25
0.90	0.25
0.90	0.50
0.75	0.50
0.90	0.60
0.90	0.75
0.90	1.00

Any percentage of sugar from 4 to 7 can be combined with these percentages.

If we thoroughly grasp the sense of what has just been said in connection with human breast milk, and the milk of animals, especially that of the cow, which seems to be the animal whose product is most adapted to substitute feeding, we shall at once see that the main question regarding substitute feeding is how to obtain the best milk, how to treat it, and how to modify it accurately. The importance of the milk supply is, however, great, and there is no doubt but that the breed of the cow, the care of the cow, of the stables and of the milkers on the farms especially used for the purpose of obtaining a proper milk supply for substitute feeding, is the keynote to success.

ALBUMINURIA IN DIABETES MELLITUS.

ITS IMPORTANCE AS A FACTOR IN THE CAUSATION OF DIABETIC COMA.*

ARTHUR R. ELLIOTT, M.D.
Professor of Medicine, Post-Graduate Medical School.
CHICAGO.

Among the secondary tissue degenerations which result from diabetes none is so frequent as lesional changes in the kidneys. No extensive autopsy reports are at hand to establish the relative frequency of renal changes in diabetes, but such as are forthcoming demonstrate in a striking manner the association. Thus out of Griesinger's 64 autopsies, renal alterations were found in 32. In the main, the changes were degenerative in character, either fatty or hyperplasic. Seegen found such changes in 20 out of 30 cases brought to autopsy, and Dickinson in 25 out of 27. No special form of renal defect in diabetes can as yet be looked on as typical, the changes being variable in kind and degree, although almost always present. The form which they assume will depend on the duration and intensity of the irritation, to which the renal gland structure is subjected. As the toxemia differs very greatly in character and degree in the different forms—mild and severe—of diabetes, so we find the secondary changes in the kidneys differing widely in their essence and microscopic character.

The most interesting histologic feature of the diabetic kidney is the hyaline degeneration of the tubular epithelium first described by Armanni, and now generally known as the cellular necrosis of Ebstein. This condition of the tubular epithelium is encountered only in severe toxic forms of diabetes. Dreschfeld found these necrotic changes in 6 out of 10 cases of diabetic coma. Other renal alterations occasionally met with in severe

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

forms of the disease are hypertrophy and the so-called lesion of Ehrlich, which, according to Frerichs and Ehrlich, consists in glycogen degeneration of Henle's loop and the straight tubes. All these renal changes may be ascribed to the action of toxic bodies of highly irritating character, such as acetone, diacetic and oxybutyric acids, etc., which are present in the blood and urine of such cases.

In the mild long-continued form of diabetes the renal changes which develop are usually those of chronic nephritis. The development of chronic nephritis under these circumstances may be explained by prolonged hyperfunction, combined with persistent but low-grade irritation of the renal structure by the saccharin urine, which lead first to hyperemia, and if long enough continued, finally to inflammation of the parenchyma and overgrowth of the interstitial tissue. In this type of the disease the renal gland changes are nutritional and degenerative, whereas in the more rapidly progressive and toxic form of the malady they are inflammatory or necrotic. In the majority of cases presenting chronic organic processes in the kidneys the nephritis is probably of the mixed type, presenting both parenchymatous changes and interstitial hyperplasia. In aged diabetes arteriosclerotic renal atrophy is frequent.

Whatever form the renal alterations may assume, they sooner or later give rise to the presence of albumin in the urine. The frequent association of albuminuria with diabetes has received considerable attention, and much statistical evidence is available.

Pollatchek	found albumin in	37	per cent.	of	cases.
Von Schmitz	"	"	63.4	"	"	"
Lecorché	"	"	50	"	"	"
Bouchardat	"	"	45	"	"	"
Von Noorden	"	"	23.5	"	"	"
Grube	"	"	40.4	"	"	"
Stokvis	"	"	40	"	"	"
Bouchard	"	"	43	"	"	"
Von Dusch	"	"	28.5	"	"	"
Rokitansky	"	"	66	"	"	"

These statistics represent an average of 43.68 per cent in which albuminuria was present in diabetes.

Attempts have been made to classify the albuminuria of diabetes. Goudard distinguishes two nosologic varieties, which he names functional and lesional, the former associated with renal fatigue with phosphaturia or with organic disassimilation, whereas the lesional is produced by some form of renal lesion. Jacobson, on similar grounds, separates albuminuria of diabetes into benign and severe.

Grube divides diabetic albuminuria into five varieties, viz.: 1, terminal albuminuria associated with diabetic coma; 2, cardiac albuminuria met with in connection with myocardial weakness; 3, senile albuminuria of arteriosclerotic origin; 4, functional albuminuria due to irritation of kidneys by the saccharin urine; 5, albuminuria associated with organic renal changes. Salles recommends an equally complicated classification.

It seems to the writer unnecessary and confusing to adopt any elaborate classification for this condition. With the exception of the rare cases of albuminuria produced by circulatory failure in patients of asthenic type, the albuminuria of diabetes may, for general clinical purposes, be placed in one of two categories.

I. TOXIC ALBUMINURIA.

To the class known as toxic albuminuria belong the cases of the severe form of diabetes which are entering the terminal stage of the disease and in which the highly irritating acid toxins of endogenous formation have produced hyaline changes of the tubular epithelium—the so-called cellular necrosis of Ebstein, already referred to. This albuminuria is never absent in the stage of organic disassimilation and in diabetic coma, although it may fail to make its appearance until the terminal stage is entered on and toxinuria becomes established. This albuminuria is never of severe grade, seldom amounting to more than a mere trace, or at most, 1 to 1,000. It usually shows some increase just before death, and sooner or later becomes associated with large numbers of hyaline tube casts. After it makes its appearance, this form of albuminuria seldom disappears again completely. As a rule the albuminuria and glycosuria bear no direct relation to each other, and in occasional cases may even stand in inverse proportion to one another. It will usually be found, however, that a direct relationship exists between the toxinuria and the albuminuria, the latter increasing or diminishing with increase or dimunition of acetone and acid toxins in the urine.

This form of albuminuria constitutes what has been sometimes known as the acute albuminuria of McGuire. Universal clinical experience associates this form of albuminuria with the advent of coma, which gives it a grave prognostic significance.

II. DEGENERATIVE ALBUMINURIA.

The second class of albuminuria in diabetes includes the vast majority of cases of this condition, for notwithstanding the greater proportional frequency of the first variety to the class of cases in which it arises, the severe type of diabetes, these constitute but a small per cent. of the great bulk of diabetes. This form of albuminuria is also the product of renal irritation, but irritation of an entirely different nature and severity. In this class of cases the sugar in the urine is the offending agent. Its potency in this respect is much less than that possessed by the acid toxins of the severe grades of the disease, but its continuous action over long periods of time, combined with renal hyperfunction, which attends the associated polyuria, in the end inevitably initiate changes in the kidney which, in their full development, constitute nephritis. In proportion as the renal epithelium is affected, albumin appears in the urine, and as parenchymatous changes are usually a first result of the hyperemia following irritation, albuminuria is a pretty regular attendant on the renal change. In many cases for considerable periods this albuminuria is not attended by any very demonstrable evidence of nephritis, and consequently it has been misnamed functional, to distinguish it from albuminuria, associated with definite and clinically recognizable renal lesions. It has been considered a development of little importance and in the presence of conflicting therapeutic indications, as between the glycosuria and albuminuria, the latter is usually neglected. After a time, however, this at first apparently accidental albuminuria is found to merge imperceptibly into a true lesional albuminuria, with impaired renal function and secondary cardiovascular developments. Hyperfunction and persistent irritation have done their work, and a nephritis of a mixed type becomes established and adds to the difficulties of the case.

It will be seen from the foregoing brief considerations regarding albuminuria in diabetes that fully a third or more of all cases of the disease manifest this symptom at some time during their course. Although by no means of itself always a sign of established renal mischief, it is never devoid of importance. It may appear so frequently without accompanying disturbance that many writers falsely regard it as a harmless

sign. As pointed out, it may occasionally arise as the apparent product of irritation of the kidneys by the saccharin urine, but should the glycosuria continue, definite renal and secondary systemic changes eventually result. In aged diabetes with arteriosclerosis albuminuria may be present from atrophic changes in the kidneys of sclerotic origin. In the late stages of diabetes, of whatever form, albumin may appear in the urine as the result of venous stasis from cardiac asthenia.

The conclusion forced on us by these considerations is that the development of this symptom is always a significant event, indicative in the mild, long-continued form of the disease of developing nephritis, and in the severe toxemic stages of diabetes we are warranted by experience in regarding it as one of the terminal developments.

A matter of great interest in connection with the albuminuria of diabetes is the frequency with which the glycosuria is observed to diminish as the albuminuria becomes more pronounced. In exceptional cases the glycosuria may even entirely disappear, thus constituting the substitutive albuminuria of Salles. Maragliano is skeptical of a true substitutive process, and explains the fact on the theory that albuminuria appears on improvement of the diabetes under treatment, because the polyuria lessens *pari passu* with diminution of the glycosuria and albumin already present but masked by the previous dilution of the urine is revealed. This view can not be seriously accepted as an explanation, because in most cases diminution of the glycosuria does not precede the advent of albuminuria, but follows it, and albuminuria is, moreover, not usually the result of treatment. A diminution in the glycosuria, even its entire disappearance, has been observed to occur as the apparent result of the hyponutrition of such complications, as pulmonary tuberculosis, etc., when they arise during the course of a diabetes. This can not be considered a similar process to that under consideration, for in the great majority of substitutive albuminurias the nutrition is not materially depressed. Naunyn's contention that this peculiar conduct of the glycosuria is analogous to the behavior of that symptom in the presence of cachexia and marasmus, from whatever cause they may arise in diabetes, is stoutly opposed by Kleen, who observes that he has repeatedly seen cases in which nephritis, though advanced, has left a fairly good state of health, with no marasmus or cachexia, but with marked diminution of glycosuria. Such cases are within the experience of most observers.

A number of very suggestive experimental observations are at hand which have some bearing on this question of the diminution of the glycosuria in the presence of albuminuria.

Achard has suggested that in carrying out the test for alimentary glycosuria we must not forget that the failure of sugar to appear after large amounts of glucose have been swallowed, may be due not solely to the vigor of the sugar-converting power as has been supposed, but wholly or partly to renal impermeability. In confirmation of this idea he reports a case of apoplexy with a small amount of sugar in the urine but a very large amount in the blood (5.1 grams per liter). This hyperglycemia he attributes to a lack of renal permeability, which was shown to be present in this case by the methylene blue test. McGuire declares himself inclined to ascribe the diminution of the glycosuria to inefficiency of the kidneys, and he suggests that the albuminuria and its accompanying renal changes may be concerned in the production of coma.

Schupfer observed in cases of combined albuminuria and glycosuria experimentally produced that more sugar was excreted by the kidney which eliminated the least amount of albumin, the excretion of urea corresponding to that of sugar. When the kidney lesion was one-sided, the injured kidney excreted albumin and much less sugar than the uninjured one.

Ellinger and Seelig demonstrated that dogs from which the excretion of sugar was constant, after injection of cantharides showed a diminution in the output of sugar, the excretion falling in one case from 7.6 to 2 per cent. At the same time they were able to establish that the sugar content of the blood was markedly increased. They think that their results prove that the kidney lesion caused by the cantharides led to a diminution in the glycosuria, while the glycemia still existed. Along the same line as the foregoing are the experiments of Richter, who, after previously damaging the kidneys, produced glycosuria by means of phloridzin and observed that the excretion of sugar almost constantly began later than in control animals, and did not reach so high a point.

In an attempt to solve the question of the existence of a renal form of diabetes Klemperer administered as much as 10 grams of phloridzin to each of ten subjects having granular kidneys, and there was no reaction in seven. That three of his patients developed glycosuria he thought might be due to portions of the kidneys having been still unaffected by the morbid process. Klemperer gave phloridzin by the mouth. Pugnat and Ravilliod administered phloridzin subcutaneously to twenty-one cases of renal disease, and in no case was the excretion of sugar normal in amount, and they conclude that with renal disease phloridzin glycosuria is either diminished in amount or entirely absent. In thirteen of the cases a marked diminution was observed, and in eight cases it failed entirely to appear. The experiments of Achard and Delamarre, performed in the same manner as the above, gave somewhat similar results. In five cases of interstitial nephritis four showed a marked hypoglycosuria, and in one case no glycosuria resulted. In four cases of acute tubal nephritis three showed hypoglycosuria, and in one case no glycosuria resulted. Of nine cases of chronic tubal nephritis five were hypoglycosuric, and four non-glycosuric.

From these collected observations the inference seems clearly justifiable that increased tolerance for carbohydrates and diminution of glycosuria in the presence of albuminuria is due to lesion of the kidney, which operates to cause diminished permeability of the renal secreting structure, not alone to sugar, but also to urea and other extractives, with accumulation of these bodies in the blood.

In the light of this deduction, an entirely new importance becomes attached to albuminuria and its associated renal changes in diabetes. The development of albuminuria in diabetes at once assumes a new and greater prognostic significance, especially in grave cases of the disease, where it may be of importance in the production of coma, by causing a heaping up of sugar and toxins in the blood. We have seen that there are constantly present in fatal cases of diabetic coma inflammatory and necrotic changes in the renal gland structure, comprising most frequently the epithelial necrosis of Ebstein, and less frequently hypertrophy with hyperemia and the degenerative lesion of Ehrlich. That these changes are not merely accidental is attested

by the constancy of their occurrence, some form being almost invariably present. We have also seen that albuminuria invariably develops before the advent of coma. Grube, Williamson, Stokvis, Kleen and others regard its occurrence at this stage as constant, and their opinion is verified by practical experience. Personally, I have never seen coma develop without albumin being present in the urine, usually associated with casts. Kuelz first pointed out the frequent association of renal casts with diabetic coma, and they are now regarded as a sign of decided significance. We may regard the albuminuria and casts, under these circumstances, as the visible outward evidence of the renal gland changes. The results of experimentation already detailed point to the fact that the kidney lesions are inimical to the glycosuria, and frequently interfere completely with transudation of the sugar. Equal proof exists that urea, and presumably other organic extractives, suffer a diminution in the urine. It is a matter of common observation that immediately preceding the development of coma, a marked fall in renal efficiency takes place. Not only does the sugar diminish in quantity, but the quantity of urine, the urea and other urinary solids suffer a decided and material reduction. Dreschfeld has observed in two cases that at the outset of coma acetone and the ferric chlorid reaction entirely disappeared from the urine. No corroborative evidence is at hand regarding this interesting observation. Certain it is, however, that preceding coma we invariably have renal conditions established with albuminuria and casts, and with decided reduction in renal permeability. To the writer abundant proof exists in these associated renal changes and clinical developments for the belief that the kidney alterations are an invariable antecedent of diabetic coma, and frequently its determining factor, by causing a sudden and marked diminution in renal permeability and a heaping up in the blood of the diabetic toxins. This view of the etiology of diabetic coma does not substitute a uremic for a purely diabetic origin, for the coma is certainly not uremic, although uremia may be a secondary contributing factor. It is frequently observed in grave diabetes that acetone and diacetic acid may be present for long periods of time without the incidence of coma, and not until the evidence of renal alterations make their appearance, does the patient develop profound evidence of coma. Experimental evidence regarding the toxicity of these bodies demonstrates that acetone, diacetic and oxybutyric acids can not be said to be toxic in the ordinary sense of the words, and that all of them can be taken by a healthy person in comparatively large amount without ill effects. It is shown, however, that if they are introduced into the blood of animals in large enough quantities they will produce symptoms closely resembling those of diabetic coma, and that they possess the power of producing albuminuria. It has been observed that acetone, diacetic and oxybutyric acids occurring in certain other states than diabetes occasionally give rise to all the graver symptoms of the coma of diabetes. It can not be doubted that these toxins are the cause of coma in diabetes, but it is the renal impermeability produced as a result of the irritation of these bodies in the blood and urine which is the final determining factor, by so increasing the toxemia through accumulation of these bodies in the blood as to initiate the coma:

CONCLUSIONS.

The following conclusions seem warrantable in the light of the facts here collected:

1. Albuminuria is a frequent development during the progress of diabetes, over one-third of all cases manifesting this symptom at some time during their course.

2. Albuminuria in diabetes may, for clinical purposes, be divided into two varieties, toxic and degenerative.

3. Toxic albuminuria is generally of acute onset, arising during the later stages of the severe forms of the disease, as the result of irritation of the tubular epithelium, producing hyaline degeneration thereof, and due to the presence of acid toxins in the blood and urine.

4. Toxic albuminuria is an invariable precedent and accompaniment of coma, and may be regarded as of the gravest prognostic significance.

5. Toxic albuminuria with its associated renal changes, is the final determining cause of coma diabeticum, by producing a heaping up of sugar and toxins in the blood, through diminished permeability of the renal secreting structure.

6. Degenerative albuminuria occurs with great frequency during the progress of the mild type of the disease, and is of renal origin and produced by a gradually developing nephritis, which arises from prolonged hyperfunction and impairment of renal nutrition.

7. The appearance of albumin under these circumstances, while of little immediate significance, is of the greatest eventual importance, as indicating the intrusion of chronic nephritis into the already manifold clinical difficulties.

8. A few cases of albuminuria in diabetes may be produced by venous stasis due to cardiac asthenia, and under such circumstances will be associated with other evidence of heart failure.

9. Albuminuria in diabetes is never devoid of importance. It may be of the gravest significance, as we have seen, and is always of sufficient import to receive the earnest attention of the clinician.

DISCUSSION.

Dr. William Krauss, Memphis, Tenn.—The percentage of cases of diabetes with albuminuria is perhaps greater than stated by the essayist, at least this has been my limited experience. I recall a case that no longer eliminated sugar on account of lost permeability, only albumin and casts. He had a horror of Bright's disease, and so I assured him that he was suffering from secondary nephritis, and under proper regimen he did fairly well. A student one unfortunate day told him nephritis and Bright's disease were one and the same thing. This depressed him so that he took to his bed and never recovered.

Dr. F. R. Weber, Milwaukee, Wis.—There is one point of great importance in this connection, the great influence of intercurrent febrile affections in cases of diabetes. Symptoms of intercurrent febrile affections, lasting three or four days, have a wonderful influence on these patients. I recall an instance

occurring in a young girl of eight years, who had diabetes in childhood, which was not a typical case at all. One evening the child was stricken with tonsillitis and died within twenty-four hours. In this case a physiologic albuminuria rapidly developed into a pathologic albuminuria, coma appearing before death.

DR. ARTHUR R. ELLIOTT, Chicago—My purpose in presenting the paper was to draw attention to the importance of albuminuria in diabetes; the association of the two having never been regarded hithertofore as having any special prognostic significance. I believe albuminuria occurring in diabetes is never without significance. In acute cases it ought to be interpreted as a sign of approaching danger, and it should under all circumstances receive the earnest attention of the practitioner. The association of albuminuria with developing diabetic coma is too invariable to be mere coincidence. The conclusions of this communication, if they be correct, make the development of albuminuria one of the most important incidents of the diabetic state.

FRACTURE OF THE UPPER THIRD OF THE FEMUR SUCCESSFULLY TREATED WITH PLASTER OF PARIS WITHOUT EXTENSION.*

L. SEXTON, M.D.
NEW ORLEANS.

Fractures of the shaft of the femur are very common accidents, despite the strength of the bone. The lower end of the bone is more frequently broken than the upper. Fractures of the upper third are usually due to indirect violence, and of the lower third to direct injury. The course of the fracture is usually oblique. Marked angular, rotary and longitudinal displacements usually attend these fractures. The lower fragment is usually drawn to the inner side and behind the upper; this tendency to deformity is greatest when the fracture occurs in the upper third.

Every kind and variety of fracture is liable to occur to the femur. On account of the large muscular attachments to the bone, displacements are nearly always present in fractures of the femur, and this is especially true in relation to fractures of the upper third, when the bone is tilted forward by the action of the psoas, and abducted and turned out by the gluteus maximus and external rotators of the thigh, at the same time the lower end is drawn upward and to the inner side by the hamstring and adductor muscles. The weight of the foot assists these adductors in the eversion of the foot, which is a symptom of this fracture. The proper appliances for treatment of fracture of the femur has caused wide and varied discussions with many diversified views; there are perhaps more special apparatus invented and discarded for the treatment of these fractures of the femur than for any other bone of the body, but the one point of extension is agreed on by all.

Recumbent position, a suitable bed with foot elevated, a hair mattress, not too soft, and immobilized retention of the fragments are indispensable to success.

The nates are prevented from sinking into the mattress by placing boards between the mattress and springs of the bed. Extension is usually obtained by cord and weight applied to the leg over a pulley attached to the foot of the bed. The foot of the bed is often raised six inches and the extension weight increased up to ten pounds in order to overcome the muscular contraction so that the fragments can be brought down together.

Many surgeons have called attention to the difficulty in approximating the fractured ends, especially when they occur in the upper third of the femur, and in maintaining them in apposition after they have once been reduced. A casual glance through our different museums will prove that this is the seat of permanent deformities and usual shortening of the fractured limb, which has caused so many suits for damages and brought out so many cork-sole shoes and criticisms on surgeons.

Dr. Allis even considered this shortening and displacement so serious that he advised immediately cutting down on the fracture and wiring the bones together. In the case of a transverse fracture with lateral displacement and overlapping more than an ordinary extension apparatus to hold it in place is required. Direct lateral and anterior pressure is absolutely essential for the proper union and keeping in place of broken fragments. Under a general anesthetic, with the patient placed on a hard table and by making firm pressure on the upper fragment of the bone, while an assistant makes strong extension and counter-extension by pulling directly on the foot and body, the fragments can usually be approximated.

Owing to the mass of fleshy muscles which encompass the bone it is rather hard to say exactly when these fragments are in apposition. Good, all-around anterior lateral support for these fractured ends is best obtained by a plaster-of-paris dressing, after the bones have once been properly adjusted and swelling has abated. Owing to the thick muscular attachments of the bone, too much padding is not indicated at this point, provided the fracture is of the simple variety. The adipose tissue and muscles soon yield to the plaster dressing, which if at first seems rather tight, is soon loosened by the atrophy of the muscles and adipose tissue under rest and continued pressure, hence moderate support as can best be had by a plaster-of-paris dressing applied all around the limb, as a rule, gives better results than the long side splint, extension and sand bag and various other appliances in use. In the treatment of these cases the double inclined plane has been practically abandoned. Buck's extension by weight and pulley is still used by many surgeons. Dr. Hamilton's preference is for a long-sided splint extending from the foot to the axilla, much after the pattern of Liston's long extension splint. Valkman's sliding foot-rest is of great assistance in treatment of this fracture in many cases.

In a recent case of fracture of the upper third in a little boy 8 years old, with marked elevation of the upper fragment accompanied by eversion of the foot and drawing up of the lower fragment, I had a most successful result by the following simple method of one plaster-of-paris dressing which was not disturbed from the time of its application a few hours after the fracture until its removal four weeks after the accident, in which we found perfect union without any shortening. The little patient in pushing a swing that in its rebound came within six inches of the ground was caught under the swing-box seat, in which five or six other children were seated, the fracture being produced by direct violence, with some, though not very great, contusion of the soft parts.

The little patient was placed on a hard table with pelvic rest, the leg being held in extension; he was thoroughly relaxed with chloroform and the fracture reduced by extension, counter-extension and manipulation. While in this position a 2-inch Z. O. plaster was applied on both sides of the leg above the knee with a loop around the heel to provide for extension in the event of shortening; several roller bandages of padded cotton were ap-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

plied around the limb thoroughly protecting the heels, condyles and trochanter and iliac spine; this batting was applied rather thin around the fleshy thigh proper, was extended around the pelvis, and up as high as the stomach, being thickly applied over the abdomen. With two assistants maintaining extension and counter-extension, plaster-of-paris bandages were applied from the ball of the great toe on around the fractured limb across the pelvis and up to the stomach. These bandages were interspersed with plaster-of-paris muck, not too wet, giving additional support between each layer.

With the pelvic rest it was not hard to apply the dressing, so that it came well up in the groin, which had been previously padded, sufficient space being left posterially for the use of the bed-pan. We were careful to sufficiently pad the abdomen to accommodate gaseous extensions likely to occur after dinner, and were particular to carry the bandage up around the body as high as the stomach, so that the point of fracture was in reality at the middle of the plaster cast. In applying the first plaster bandage the upper end of the fragment was depressed by firm pressure, and, as said before, the bandages were reinforced by the additional plaster at the point of the break. When the plaster had set, we found that the length of the two limbs were exactly the same; which relative position remained until a cure had been accomplished, so that at no time was it necessary to add any weights to our adhesive straps which had been applied for extension in the event of any shortening.

The patient while confined to the recumbent position could move around on his hard mattress with comparative ease, the dressings did not become soiled from any source during the month's treatment, there were no bed or pressure sores in the case; only two or three casual visits were made during the treatment, and the result, as seen by the patient before you, was all that could be expected.

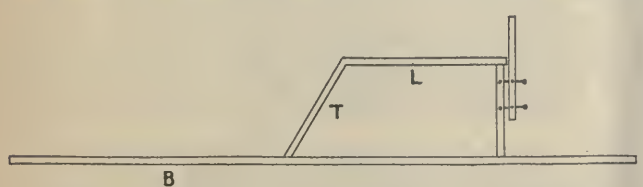
This case has been reported to show the extended use of plaster of paris in treatment of fractures of the femur, especially in children; its advantages are: its cheapness, the ease with which it is applied, its perfect adaptability to the shape of the limb, combining the good effects of an all-around splint, its cleanliness; it is a one-dressing treatment with nothing to get out of place, and the splendid results which follow its perfect application should commend it to surgeons in suitable cases in preference to the numerous complicated appliances recommended for the treatment of fracture of the femur, especially in children.

The second case brought before you is an engineer with fracture of the lower third, but treated with the plaster dressing without any extension, and, as you see, with no shortening, and with complete recovery within seven weeks' time.

I will show you another patient treated without any extension method. He was an engineer on the Illinois Central Railroad, and in a collision jumped from his engine into a pile of cross-ties, the result being a backward dislocation of the knee-joint and fracture of the lower third of the femur.

I dressed the wound in plaster of paris, as in the first case. We did not have quite enough padding on the first dressing, and we had to remove the bandage and put on a second plaster-of-paris dressing on account of the swelling.

The ankylosis observed in the knee is not the result of the fracture, but is caused by the extreme backward dislocation of the joint. It has only been about seven weeks since the accident occurred, but there is not a particle of shortening, as you can observe by examination, and by the use of the tape measure. The halt in walking is a result of the dislocation, and not of the fracture. Considering the double damage of the fracture and the dislocation, the patient certainly was fortunate in the termination of this case, as he soon expects to be riding on his engine, doing his regular duties as engineer.



DISCUSSION.

Dr. John P. Lord, Omaha—I think the more expert we become in the use of plaster of paris the more constantly do we find an increasing field for it. While I am not prepared to say that all cases of fracture of the femur should be treated by plaster, yet I think you can perhaps treat the greater number of them in this way. Fractures just below the trochanters, for instance, I would not think of treating by the use of the plaster cast, because the extreme upward displacement of the proximal fragments would preclude the possibility of a good result in at least many of the cases. It has been my experience that the so-called intracapsular fractures are best treated by the plaster. Extension can also be used in addition to the plaster, if necessary, which I think is an excellent idea, and is too often neglected in the cases in which plaster is used. I think we can do with the plaster all that is required. I consider fracture of the femur in children comparatively easy to treat. I think this principle should govern our actions in the treatment of these cases. We should first reduce the fracture to as near a perfect position as possible, and then put on such a dressing as will maintain absolutely the proper position of the fragments, a dressing, indeed, that will continue to maintain this position of the fragments. The old-fashioned method of using sandbags and other splints relatively insecure, I think, at the best is poor practice. You can not depend on such things. We have all seen our preceptors adjust sandbags and rearrange the dressings every day. If there is anything that will encourage non-union it is that sort of thing. I think plaster does accomplish the result in a more definite and perfect manner than any other method.

Dr. W. W. Grant, Denver—The essayist referred to Dr Allis' declaration as to the difficulty of maintaining the apposition of the fragments and the necessity of cutting down and wiring the ends. In an article which he published several years ago, Lane of London stated that it was not so much muscular action that caused the displacement as it was the inflammatory conditions and blood about the ends of the fragments. In consequence of this Dr. Lane advised the cutting down and wiring the fragments—of course, under the most perfect aseptic conditions. I believe this practice often desirable in fractures of the elbow joint. However much truth there may be in his declaration that it is due chiefly to blood clot and to inflammatory conditions, we do know that the best results so far obtained have been by some form of extension with fixed apparatus around the limb. The old Buck method is today not improved on in the ordinary treatment of fractures of the shaft of the femur, coupled with the application of such splints as we may see fit to use. I would hesitate to use plaster immediately in most fractures of the femur. I believe it to be a better surgical procedure to wait until the inflammation has subsided. We know that swelling results immediately after the accident and after four or five days it has usually subsided. There will be no union during this time, and it is best to wait until the swelling has subsided before applying the plaster. It is particularly important during this time that you should see the condition of the limb every day. Legs have had to be amputated because of the failure or inability to see the patient often after the application of the plaster. Therefore, one loses nothing by delaying the application of the plaster cast for this length of time. I believe in these cases there is a better dressing than plaster—silicate of potash. It can be applied just as easily, but it does not dry so quickly, and will require several hours to harden perfectly. When the silicate of potash is dry it is very light and is just as efficient, and if you prefer the ambulatory treatment there

is no comparison. It is so much lighter, cleaner, much neater and more easily and quickly removed.

DR. JOHN W. BRANDAU, Clarksville, Tenn.—The method which I will describe I have found very efficient in three cases of fracture of the femur in children. I exhibited a model of this splint two years ago before the State Medical Association of Tennesseee. In the first place I make a board splint out of some light wood, about three-quarters of an inch thick, as wide as and a little longer than the patient's body, so as to give rest to the head and extend a little below the patient's foot with sound limb extended. The next thing is to make a thigh splint, which is firmly attached to the body splint at such an angle as will hold the fragments best in apposition, and on the side corresponding to injury. Then a leg splint running parallel to the body splint, with proximal end attached to thigh piece, with a support at the lower or distal end of the leg splint which rests on and is fastened to the body splint, thus forming an irregular arch. The splint should be made by measuring the sound leg and thigh and may be made longer or shorter, according to the amount of extension one wants to apply. The extension of thigh is also regulated by the padding one puts on the leg piece. If necessary, one can apply a foot splint adjusted so as to make extension on the leg, if that is also fractured, as per drawing below. The whole splint is then padded in order to make it as soft as possible for the patient's body and padding secured by roller bandages. The patient is then placed on the splint on his back, and the body firmly fastened to the base splint by a roller bandage in such a manner as to immobilize the trunk, which I think is important in the treatment of fractures of the femur in children. The entire limb is next secured to the splint by a roller bandage. In addition to this splint one should use short

B.—Body or base splint. T.—Thigh splint. L.—Leg splint.

coaptation splints to the thigh anteriorly and laterally, so as to hold the fragments more securely in position. To secure these splints in position either a roller bandage, as above suggested, or adhesive strips may be used, and I find the latter convenient because they will not slip. The sound limb should be fixed to the body splint by strips which can be readily untied to allow the limb to be flexed in order to cleanse the child, etc. The splint can be easily made, nothing being required but a hatchet, nails, some light boards, cotton and bandages. The little child with this splint can be applied to the breast, carried out in the open air, and can be placed on either side in order to prevent hypostatic congestion of the lungs. I have had no trouble with the circulation in using this apparatus. The part on which the patient's buttocks rest may be covered by ruber cloth, or a fenestrum may be made in the cases of older children. The end of the apparatus on which the head rests should be kept a little more elevated than the foot, in order to prevent the dejecta from running back under the patient's body. The apparatus is very light when made of white pine or poplar wood.

DR. J. W. ANDREWS, Mankato, Minn.—I don't think that anything has come before this convention of greater importance than this subject of the treatment of fractures, and it just occurred to me, as Dr. Grant was speaking, that if every surgeon would follow his plan and have less to do with the side splint and complicated apparatus, the results would be far better. It is not an easy matter to get good results in fractures of the femur. It is probably not very difficult to give the patient a fairly useful limb, but to get results without shortening and without deformity is not so easy to do. And while a quarter of a century ago a physician could very well be content with some shortening, a surgeon who gets much shortening to-day is not inculpable. I well remember hearing the late Moses Gunn of Chicago, after some one had read a paper before a meeting of the American Medical Association, in which he reported having gotten a perfect result; Dr. Gunn rose from his seat and said he wished to place himself on record as saying that no man could get a perfect result in fracture of the femur. That day is past, and at the present time, where we have a fairly useful limb, but there is some deformity, we do not consider that we have gotten a perfect result. As Dr. Grant has said, it is most important to keep the limb so that it can be seen for the first few days until the inflammation, if any, has subsided, during which time the old methods of extension can be applied, after which time the extension should be continued and the limb placed in plaster of paris. I believe that if that method is carried out, the results produced by it will be as good as can be produced by any other method of treatment. In reference to the objections made by Dr. Grant as to the weight of the cast and the untidiness of the plaster-of-paris dressing, little need be said for it is a small objection, and so far as having an apparatus that our patients can walk around with, or the ambulatory treatment, I do not believe that many surgeons care to have their patients with a fracture of the femur walk around much during the first three or four weeks at least.

DR. J. D. MAURY, New York—I was very much interested in the description given by Dr. Brandau of the splint which he applies in these cases, because it suggests to my mind the straight angle chair used by Sayre to relieve adult patients who have been in bed and are suffering from hypostatic pneumonia. In the City Hospital, New York, we simply used an old rocking chair, with a hole cut in the seat for the movement of the patient's bowels. The patient is then placed in it, being sure that the seat of the chair is longer than from the legs to the region of the lower back, and the patient is then arranged in such position as will give him comfort. Gravity is sufficient in these cases to give all the extension necessary. In regard to the plaster of paris, we have been using a modification of this method in New York, which seems much superior to the "glass" bandages. About a year ago I learned from a wall decorator that they used dextrin in making the cornices of the modern buildings and it occurred to me to incorporate some of this in the plaster of paris. We have used it in 10 per cent. strength by volume, simply mixing it dry and making bandages of crinoline in the usual manner. It is a very useful addition and in a measure does away with the weight of the plaster of paris. I found that it was not an original idea and that it had been used a good many years ago by Velpeau, but I learned that Dr. Weir and others in New York were not familiar with its use, and I thought probably the members of this section might not be. In the treatment of those forms of injury to the lower extremity in which the patient may be allowed to walk without crutches it is invaluable. It is also applicable for the making of spondylitis jackets. Put on the ordinary plaster of paris and then dry it. We have been drying it by one of those torches used by painters to clean off paint, we then put on about one thickness 10 per cent. dextrin crinoline bandages. This gives the plaster a yellowish hue and makes it as hard as adamant. It is not quite so porous as the plaster alone. At the Columbia Laboratory there are some experiments being made to determine the relative porosity of the two substances. Clinically we find that it does not make the cast hot enough to interfere with the comfort of the patient, and if such should be the case, fenestræ may be placed at such frequent intervals as to more than compensate for any such limitation. The cast, although very hard and tough, cuts very readily with a sharp pruning knife if the line of section be thoroughly wet with water.

DR. D. W. CROUSE, Waterloo, Iowa—I had a new experience the last year in a case of ununited fracture of the femur that had non-union after a varied treatment of three months. The fracture was close to the condyles and was comminuted. The patient was 18 years of age at the time of the accident

and in vigorous health. The attending surgeon placed the leg in plaster cast from the first, for six weeks. When the cast was removed it was found to be ununited; a new fixed dressing was applied and the patient put on crutches and treatment continued for six weeks, with the patient walking about, with the same unsuccessful result. He was again placed in bed with pulley extension for six weeks more when he was brought to the hospital for the purpose of cutting down and wiring the ends together. The ends were found separated by muscular tissue and fascia a full inch. The ends of the bones were uneven and some pieces of bone loose from the shaft entirely—the ends of the bones were sawed off and approximated and wired. He did well for 10 days when he suddenly developed a hemorrhage and lost a large amount of blood before the case was under control, and in great danger of his life. A forced amputation was made in the middle third of the femur and transfusion of saline solution made at the same time and although nearly pulseless in the beginning, he was put to bed in rather a better condition than when the operation was commenced. Examination of limb amputated disclosed what was already known that the popliteal artery had beaten against the irregular crest of the fractured bone and had worn the coat of the artery through and nothing but amputation was left to be done. The lesson taught is that the posterior fragments should present no projection, the bone is to be lined with the posterior aspect of limb in adjusting a fracture near the condyles of the femur.

Dr. Luther Sexton, New Orleans—A liquid glass dressing is out of the question in a hot climate like this where it would soon become moistened by perspiration. I do not know how it would do in a cold climate, or how it might be with the dextrin, but I have never seen a liquid glass dressing applied to the fracture of the femur as a permanent dressing. The doctor's conception in regard to the patients walking around with fracture of the femur, I think, is remarkable and must apply to the convalescing period. We usually confine our patients in bed for at least one month, during which time we expect absolute quiet. After this walking and the upright position is encouraged. In regard to plaster fixation I claim that the mistake made in applying the dressing in many of these cases is that they do not carry the support up high enough. In these cases the plaster of paris was carried as high up as the stomach, the stomach, of course being well padded. We put on about as much plaster above the fracture point as we did below. I am not claiming that this is the proper dressing in all cases. I applied the Z.O. plaster in order to produce extension, if I need it. The little boy is as nimble as ever, and though the fracture was in the upper third of the bone there is no deformity or shortening. In the application of this plaster dressing, I believe it is absolutely necessary to have an assistant hold the fractured bones in position until the plaster-of-paris dressing is firmly applied. One of the points that I would like to emphasize is that you should have more of the plaster of paris above the fracture; do not have the dressing all below the fracture. In the case of the little boy, the point of fracture was actually in the middle of the plaster-of-paris cast. Now, in regard to the cast becoming soiled and not being hard enough, I have usually found it hard enough when it comes to take it off. If you wish to make it harder and render it so that it will not soil, you can paint it over with shellac. I have the cast preserved which was on the little boy, and the only soiling it got was from the money he put into it. He used it as a savings bank, for he got a dollar a day for keeping quiet, which was a great help in the treatment.

Aid to Catheterization.—Schroen found that he was able to introduce the catheter in a rebellious case in which an operation seemed the only resource, by connecting the catheter with a fountain syringe. Raising the bag so that the pressure was strong as the tip of the catheter reached the constriction, the force of the water distended the walls of the urethra and allowed the ready passage of the catheter, as he describes in the *Allg. Med. Ct.-Ztg.*, lxxi, p. 659.

SUBTROPICAL TRACHOMA,

WITH SPECIAL RELATION TO A NEW REMEDY IN ITS TREATMENT.*

RUFFIN A. WRIGHT, M.D.
MOBILE, ALA.

Discussion of the nature of trachoma with its relation to follicular conjunctivitis or gonorrheal ophthalmia does not lie within the limits of these remarks. Where great authorities differ so widely as to etiology facts yet unknown must be discovered before a consonance of opinion prevails. Trachoma, chiefly in its clinical aspect, occupies the substance of my paper.

Consideration of the disease is based on the following hypotheses:

1. Trachoma is a distinct disease, characterized by a granular and hypertrophic condition of the palpebral conjunctiva and its transition folds, usually with signs of ulceration.

2. It tends to progress in a fixed manner, varying only in degree.

3. Certain complications and sequelæ mark its course and termination.

4. Trachoma is contagious. It is a separate and distinct disease from follicular conjunctivitis.

5. It is capable of being beneficially modified, even cured, by appropriate early treatment.

After seeing the clinical aspect of trachoma in its strongholds abroad, observing its ravages and extent among the rural classes of northern and southern Germany; remarking its sinister results among the inhabitants of the metropolitan slums, such people as form the majority seeking aid in Vienna's great eye clinics, I then turn to a six years' experience in southern Alabama, and am forced to the conclusion that the type of the disease, in this latter locality, is milder in form, less frequent in the more serious complications and less disastrous in its final results than in the older countries.

Only in rare instances, chiefly among foreigners, among what might be called our Polish Jew contingent, have I seen cases of such severity as I formerly regarded as common types in European clinics.

Regarding the question of racial immunity, my evidence is entirely negative. I can only say that in spite of handling many colored patients I have never yet seen a case of true trachoma among negroes.

Some three weeks ago I saw a negro boy, aged 5 years, who exhibited extensive, exuberant granulations of both lids. Close inquiry elicited the fact that the lids had never entirely recovered from what had probably been an attack of ophthalmia neonatorum. This is the nearest approach to a suspicion of trachoma that has come under my observation in the negro race.

My colleague, Dr. William H. Sanders of Mobile, now state health officer of Alabama, tells me that in an experience of about thirty years he can not recall a single instance of a well-defined case of trachoma in a negro.

While considering our form of trachoma as less severe than in many other localities, no evidence is present to cause doubt of its ready contagion. Usually more than one member of a family is affected.

While in the northern and eastern cities much has already been accomplished to curtail the ravages of trachoma, I have yet to hear of a southern municipality whose boards of health have inaugurated any system of

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

inspection at all adequate for its recognition, much less its exclusion from their public schools.

The disease is becoming more prevalent. For, although my percentage of patients handled has not been appreciably greater, I have seen more cases of trachoma among school children within the past eight months than during the preceding two years.

In view of the fact that the laws of the United States recognize trachoma as a contagious disease, denying the right of admission to immigrants suffering from it; that health authorities of New York city exclude children suffering from trachoma from the public schools, it is quite time that all of our health boards should take cognizance of its existence in their midst, and should inaugurate the necessary steps to control its further spread.

The number of therapeutic agents whose proven efficiency in combating eye diseases renders their use almost universal, is infinitely limited. Twenty familiar names would fill the list ordinarily used by the ophthalmologist. New remedies, promising much, fulfilling but little, are constantly coming under notice.

We can be well satisfied if one in twenty, even one in fifty, of these new agents finds a useful, permanent place in our therapeutic armamentarium.

Before the final acceptance of a new remedy it must pass the critical judgment of more than one competent observer. It is well that physicians, from the nature of their studies and environment, possess in unusual degree the analytical or critical faculty. They are loathe to accept evidence save where it is substantiated by either a wide or their own experience. Thus a safeguard exists against the too ready acceptance of new remedies. But when a recently proposed drug or agent proves beneficial they are ready to receive it gladly, so that after a longer experience it assumes its proper sphere of usefulness, and receives the esteem of a trusted and valued friend.

Cocain was once an untried drug. Which of us could practice without it? Eucain more recently has been gladly welcomed. A sense of loss would follow were adrenalin eliminated from our list.

It is unnecessary to recapitulate the well-tried remedies that are universally recognized as aids in combating trachoma. Few of us probably do not place the salts of silver, copper and alum at the head of our list. Zinc and lead, even, with their derivatives, lend us frequent aid. Used correctly in proper proportion at the right time, they all have their places. But every one of them possesses certain defects, certain limitations.

In the selection of a remedy, particularly in private practice, something more than results must be regarded. It seems to me that chief among these is the active, willing co-operation of the patients and of their families. The treatment of trachoma is, at best, long and tedious. Few patients can, with convenience, visit the physician for daily applications. Home treatment is, as a rule, submitted to badly, unwillingly and irregularly; for the applications are painful and the patient naturally reluctant to apply them.

In the new remedy which I bring before your attention I do not claim a panacea for trachoma, not even that it is in every way superior to all of our other remedies. Nor do I claim originality in its use. But, so far as my knowledge goes, I am the first man in America to give it a trial. This belief is tenable because in July, 1902, Merck informed me that he would have to import it, and I did not receive it until nearly three months later. Having used it now for seven months, its results seem to justify placing it side by side with our best remedies.

I speak of copper citrate. The points claimed for it, if I can establish them, are worthy of attention.

1. It produces absorption and disappearance of granulations and hypertrophied papillæ quite as rapidly as other applications.

2. It produces less irritation in the lids; less pain and discomfort to the patient.

3. Important, and a corollary to its almost painlessness, patients will use it regularly in home-treatment. Even a nervous mother will apply it in the eyes of her spoiled darling. What greater encomium can be pronounced on a treatment of trachoma! For we all recognize the vital importance of systematic daily applications in the eradication of this treacherous disorder.

Now let me give proper credit to Dr. F. R. Von Arlt, the originator of the copper citrate treatment. He published a short paper on the subject in the *Centralblatt für Practische Augenheilkunde,* March, 1902. Of this paper I made an English abstract, which was published in the *Mobile Medical Journal,* June, 1902. Dr. Von Arlt uses by preference silver citrate, instead of silver nitrate in cases of ophthalmia neonatorum trachoma with secretion, and other allied conditions. He was led to the trial of copper citrate on account of the analogy between copper and silver salts. His description of the salt is as follows: "Copper citrate is a light, finely divided green powder, containing 35.2 per cent. of copper. It is sparingly soluble in either cool or hot water, about 1-9,143, slightly more soluble in 1 per cent. sodium chlorid solution, i. e., about 1-7,700. It was first prepared by Guy Lussac in 1832, and so far as the author knows, its therapeutic properties have never before been utilized. At first the powder was mixed with milk-sugar (1-20 to 1-10. Later used ointment form with, as a vehicle, the ointment of glycerin with starch. He has found it specially useful in trachomatous pannus and ophthalmia neonatorum. Profuse secretions, in all cases, must first be removed by silver citrate, silver nitrate or some other similar preparation commonly used for this purpose. Contraindications are afforded by corneal ulcers and by internal or external treatment with the iodin preparations." The following statement he places in italics. With it I thoroughly agree: *"It does not cure trachoma more quickly than other non-operative methods."*

I have used the copper citrate, chiefly in early uncomplicated cases of trachoma, in the form of an ointment, the strength varying from 3 per cent. to 10 per cent., with white vaselin as a base. The results have been excellent, as the following statement of cases will show.

Of course, the period of trial (seven months) is too short to admit of a final verdict as to its curative powers. Of the cases treated only nine have been discharged as cured, while six are still under treatment, progressing quite as favorably, and with far greater personal comfort than under former methods.

During the months of September and October, 1902, I began with five cases, early in November with three, late in November with one case. These cases were all in children ranging from 5 to 14 years of age. Eight of these cases were early, simple forms of trachoma, without serious complications. One was a severe case, complicated with pannus. The eight simple cases have been discharged for a period of from four to eight weeks. At present writing seven of these cases show no sign of remaining granulations, and no scarring. In one case where the granulations were extremely large and plentiful, expression with Knapp's roller forceps preceded the applications. Here some slight scarring is noticeable.

The case of pannus had been treated for six weeks before beginning with copper citrate ointment. The clearing of the cornea was more rapid after beginning its use. For more than three months now the opacities have almost disappeared, but a slight cloudiness remains, which will doubtless be permanent.

While the patients can open their eyes and bear the light, going about their usual duties or pleasures a few minutes after the ointment has been rubbed into the conjunctival sac, I have found that the best plan for home-treatment is to apply the remedy at bedtime, letting it remain in the eyes during the night. Only a few cases find this too irritating. The majority of patients will tolerate the application twice a day. An intercurrent coryza or febrile state necessitates the discontinuance of the ointment for a few days at least. While usually beginning with the 5 per cent. ointment, for I have practically abandoned the 3 per cent. strength, except in very nervous children where it is first necessary to obtain their confidence, I believe that the majority of patients will readily tolerate the 10 per cent. strength from the inception, just so soon as excessive secretion has been allayed by one of the silver salts.

I trust that those of you who take interest in the subject, who possess the facility of large clinical material, will ere our next meeting give copper citrate a trial in trachoma.

DISCUSSION.

Dr. James W. Dunn, Cairo, Ill.—After making the statement that I have seen two cases of genuine trachoma in what I considered to be pure blooded negroes, I would like to take up the subject of treatment of this disease. It is this that appeals to us most forcibly as practitioners, and is the feature on which we will all probably differ from the one who has just read the paper and on which you will likely differ from me.

The treatment may be divided into that used before the appearance of the granulations and that applied afterward. We can not diagnose this trouble with certainty, of course, before the granulations appear, but there is certainly an antegranulation period which lies between the beginning of the irritation produced by the cause of trachoma and the appearance of the granulations, during which we certainly have a chance to abort the disease by the application of germicidal remedies, as nitrate of silver, etc., else all of our theories that the disease depends on a germ are exploded. Indeed, I think it safe to say that all of us, many times in our practice, have aborted cases of trachoma in this stage when we simply suspected granular trouble, by the application of suitable solutions of strong germicidal agents.

After the appearance of the hyaline granulations there is nothing that remedies this morbid process with the facility and safety of the roller forceps. With this I am sure the profession generally will agree. However, I go a step further in saying that the advantage gained by the expression of the granules is not the only one. By the judicious use of this instrument we can so disturb the elements entering into the tissue organization causing the hypertrophy as to bring about the absorption of these elements themselves. It matters not whether we consider that the hypertrophy is due to the formation of new tissue from new cells, or to the conversion of one class of cells into another, certain it is that the hypertrophy and subsequent contraction can be removed and avoided in the proportion that we are able to bring about the absorption of the elements deposited in or under the conjunctiva. The roller forceps, firmly and steadily applied, can certainly assist very materially in this.

Then I may say further, that this is not the only good produced by the use of the roller forceps. In the old chronic cases their application is followed by an acute inflammatory reaction that has practically all the advantages of a jequirity inflammation without any of its disadvantages. So I almost always apply the roller forceps in trachoma. If it is an acute case, the application is made chiefly to express the contents of the hyaline granules; if it is a chronic case, the greatest desideratum may be the removal of the hypertrophy for which they are then used; but in most cases, however, both indications will obtain.

After the application of the forceps, it is not a question of choice of remedies. Any application that has a tendency to reduce inflammation will do good. Ichthargon, protargol, the milder boric acid, or the preparation the Doctor has mentioned in his paper will suffice. In conclusion, I desire to commend this method for those old chronic cases in which every kind of application seems to irritate and make matters worse—the very class of cases in which the profession at large is accustomed not to use it. The application, as I have said, is followed by an acute inflammatory process which results in less hypertrophy, and, consequently, much less contraction of tissue than would otherwise follow. So, to sum up, my method of treating trachoma is the roller forceps almost invariably, first, to express the contents of the hyaline granules and, second, to bring about absorption of the hypertrophy by producing an acute inflammatory reaction and by the mechanical disturbance of the elements undergoing the process of tissue formation in the hypertrophies.

Dr. Adolph O. Pfingst, Louisville—As to the clinical features of the case I would like to say a word about the differential diagnosis, because I think there is much obscurity in this respect. In my first observations of this disease cases were spoken of as trachoma which, according to my present ideas, were not trachoma at all. I got my first teachings in Berlin and in New York, and I believe now that the cases that were called trachoma in Berlin were not trachoma. To my mind the slight granular appearance and cell accumulation in the conjunctiva were not the follicles of true trachoma. I differ with the author as to its occurrence in Berlin. My experience was that there was very little trachoma there; mostly such cases as strayed in from Russia and Egypt. I was told there that the cases were rare and that there was doubt whether the proper diagnosis was always made. You have all seen cases where the entire lower fold of conjunctiva was filled with sago-like swellings and where the upper lid was not affected. I have seen cases of this kind called trachoma. The ready response of these cases to treatment is evidence that they are not trachoma. I have seen, with Dr. Ray, a case of true trachoma in a negro.

I congratulate the Doctor on his success with his new treatment. While the number of cases so treated is as yet small, the results are encouraging, as it is difficult to get patients to use these remedies at home which are usually employed in the treatment of trachoma. I believe that the greatest advantage of the essayist's treatment is the ease of its application.

Dr. Herbert Harlan, Baltimore—I had a very unique experience with a remedy that could not be applied in most cases. Three Russian immigrants were detained by the authorities because of the trachomatous condition of their eyes. On the second day after admission to the hospital two of them, children aged 3 and 5, broke out with measles and the disease had a most remarkable effect on the trachoma without any other treatment and in three or four weeks they were allowed to proceed to their homes. The father, however, who had had measles before, had to go through a long course of treatment. There is no doubt in my mind that the measles had a remarkable curative effect on the trachoma.

Dr. S. L. Ledbetter, Birmingham, Ala.—I see a great many cases of old cicatrization occurring as a result of trachoma that is evidently the same type we see elsewhere, but in the recent cases treated according to modern methods they get well without these bad results. The cases appear to be rarer than we are taught to believe, but I think that perhaps it is due to the treatment. I am of the opinion that trachoma is trachoma whether occurring in the North or South.

Dr. Ruffin Wright, Mobile, Ala.—I did not mean to speak of subtropical trachoma as a distinct disease, but only to imply that the type with us in the South was of a milder

form than what is seen in other localities. Regarding its prevalence in Germany, in one village where I spent the night the landlord and his whole family had the disease, and they said they did not believe there was a family in the town that had not had it.

As to the matter of its treatment in the incubation period, it is difficult to prove what a case would have been if you aborted it. I do not think much of aborting remedies; it is like aborting a case of pneumonia or typhoid fever.

As to the expression of the granulations with the roller forceps, it is only occasionally necessary, always results in more or less scarring, and unless the granulations are very large we gain nothing except to hasten the healing process.

I do not claim that copper citrate brings about more rapid absorption than the old treatment where the latter is applied daily, but I claim that it is a remedy that the patient will apply daily. There are less than 10 per cent. of cases that will come for daily treatment, and therein lies the benefit of this method of treatment.

CONTROL OF SUPPURATION IN THE ANTERIOR SEGMENT OF THE EYE.

BY THE INSERTION OF IODOFORM INTO THE ANTERIOR CHAMBER.*

E. C. ELLETT, M.D.
MEMPHIS, TENN.

In 1897 Ostwalt introduced a method of combating purulent inflammation of the anterior segment of the eye by inserting iodoform into the anterior chamber, and he also showed that when this was done on a normal eye it was not followed by any bad effects. The method has been occasionally referred to, but in the available literature only three allusions to it could be found. Ostwalt[1] again experimented with it in 1901 by placing rods of iodoform in the anterior chamber of a rabbit's eye, and "some time later" injecting a culture of staphylococcus or streptococcus. Purulent inflammation was prevented, but not having the original paper at hand, the facts as quoted from the abstract are vague to the point of uselessness. Romer[2] reports the use of it in three cases. In two cases of staphylococcus infection of the anterior chamber its use was followed by a cure of the condition, but in a case of cataract extraction infected by a "peculiar bacillus," it did no good. In five cases Goldzieher[3] controlled suppuration by this means, but again an abstract is my authority, and there are no details. In the hope of learning something definite of this method and its limitations, the experiments which I will recite were undertaken.

The almost uniform failure of our efforts to control the progress of infection after cataract extraction is well known, and it was particularly in the management of these cases that I hoped to get some help. As the infection in these cases comes, as a rule, from without, that is, from the conjunctiva, it seemed best to try to produce experimental infection in the same way. Repeated attempts to do this by making a corneal incision and rubbing over it a culture of staphylococcus, gave but one positive result out of a dozen attempts, and the method was then abandoned. Introduction of a portion of a culture of staphylococcus by means of a platinum wire loop passed through a corneal incision gave but little better results, and was discarded for the method of injecting into the anterior chamber with a syringe either a small particle of an agar culture, rubbed up with distilled water, or a few drops of a bouillon culture. It was astonishing to note the difficulty with which a successful inoculation was achieved. Staphylococci seemed to be hardly pyogenic in rabbits, so little reaction did they usually cause. In only two eyes did they produce sufficient reaction to be of use for the purpose of this study. Injections of streptococci were more successful, but by no means uniformly so.

The iodoform rods used in these experiments were made of gelatin containing 50 per cent. of iodoform. These substances are mixed hot and poured on a clean tin plate to harden. The resulting film is then cut into the required sizes. The procedures on the eyes were carried out under local anesthesia, and with the usual antiseptic precautions.

Experiment 1.—A single iodoform rod was introduced into the normal eye of a rabbit through a puncture in the cornea near the limbus. In two minutes the gelatin had dissolved and the liberated iodoform had settled to the lower part of the chamber. On the second day it was still to be seen surrounded by a bead of clear lymph. On the third day this exudation had lessened in size, but not till the fourth day was any absorption of the iodoform apparent. On the thirteenth day it had entirely disappeared. The pupil was active and the eye entirely normal.

Experiment 2.—A pure culture of streptococcus was injected into the anterior chamber of a rabbit. The next day a mild, plastic iritis was present, but this had subsided by the fourth day, when the injection was repeated. Four days later only a slight reaction with some exudation near the corneal wound having been produced, a third injection was made. A prompt reaction followed, iritis with abundant exudation and roughness of the cornea being noted on the second day after the third injection. The cornea regained its luster and then became covered by a vascular layer like a pannus, extending from the periphery toward the center. This did not appear until the sixth day after the successful inoculation, and took ten days to completely cover the cornea. The exudation in the anterior chamber finally almost filled the chamber, leaving a little clear portion in front and behind, but touching the cornea. While in this condition on the eighteenth day after the successful inoculation the animal was killed by rats and the eye destroyed. There was no conjunctival chemosis or swelling of the lids such as we see in panophthalmitis, though the rabbit lost flesh and seemed to suffer from systemic infection.

Experiment 3.—After two unsuccessful attempts to infect with a culture of staphylococcus a drop of a culture of *Streptococcus erysipelatis* was injected into the anterior chamber. In five hours iritis with exudation was noted. On the fourth day the exudate had collected to some extent in the lower angle of the anterior chamber (hypopyon), though the aqueous was never very clear. On the fifth day the pannus began to show at the corneal periphery. On the seventh day two iodoform rods were introduced into the anterior chamber through an incision near the limbus. These were invisible after 24 hours. No material change being noted in the eye, two more rods were introduced on the ninth day. The pannus continued to advance and the exudation in the anterior chamber to increase. On the nineteenth day the cornea was covered by the pannus and was bulging from the pressure of the exudation. On the twenty-first day the cornea sloughed, the slough separating on the twenty-second day, exposing a white, pasty mass in the anterior chamber, a culture of which showed streptococci in a state of division. The eye cicatrized and healed, a large scar occupying the site of the cornea. There was never the clinical picture of panophthalmitis as we see it in the human eye. The rabbit emaciated considerably and died. A culture of the blood made during life showed streptococci.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

2. German Ophth. Soc., 1901. Arch. Ophth., xxxi, 44.
3. Centralbl. f. Augenheilk., xxv, 71. Arch. Ophth., xxx, 685.

Experiment 4.—Inoculation by injecting a few drops of a culture of *Streptococcus pyogenes* into the anterior chamber. Iritis appeared on the second day, with cloudiness of the aqueous and the appearance on the fourth day of a mass of exudation in the anterior chamber near the wound of inoculation, together with a hypopyon in the lower angle of the chamber. On the fifth day the pannus before mentioned began to spread over the cornea, and on this day two iodoform rods were put into the anterior chamber. Tenth day, no change noted till to-day, when an additional yellowish mass of exudate was seen on the iris below the pupil, while above the pupil was a larger clear mass like the exudate seen in spongy iritis. The cornea and aqueous seemed clearer. Three more rods were put into the chamber. The next day (eleventh day) eight or ten small yellow nodules were seen on the iris, aqueous clearer. The vascularity on the cornea had advanced. On the thirteenth day, no further change being apparent, four more rods were put into the chamber; fifteenth day, no change except the pannus was much less dense. On the nineteenth day a decided clearing of the cornea had taken place, and the exudation was somewhat hour-glass shaped, with the smallest part in front of the pupil. Twenty-first day, cornea about clear, pupil occluded and the exudate was an oval yellowish body. Twenty-third day, except for a small central mass about as long as the diameter of the normal pupil, the anterior chamber was clear. Twenty-seventh day, the rabbit died. A section of the eye is shown. A culture of the blood on the twentieth day showed streptococci. There was emaciation and evidence of systemic infection.

Experiment 5.—Three injections of a culture of streptococcus were made before more than a slight irritation was produced. The reaction appeared on the third day after the successful inoculation, whereas it had, in other experiments, appeared on the first or second day. The reaction was marked on that day, with an abundant diffuse exudation into the chamber. Four iodoform rods were introduced. Fourth day, the exudation was thicker and settling as an hypopyon below and forming a mass above near the wound of inoculation. Put in two more rods. Fifth day, some of the iodoform put in on the preceding day was still visible. No change in the condition of the eye. Put in two more rods. Eighth day, the iodoform put in the eye on the fourth day was absorbed, but that put in on the fifth day was not entirely absorbed. The pannus had advanced but very little on the cornea and the exudation masses were decidedly less in quantity and less dense. Ninth day, the eye looked clearer, the exudation showing only as a slender oval mass in the center of the chamber. Tenth day, the mass of exudate was but one-half as large as on the preceding day. It was rounded and about the size of the normal pupil. The rabbit was killed by rats that night and the eyes destroyed. Systemic infection had apparently occurred from a previous experiment (No. 2), but for the last week of his life the animal was livelier, ate better and seemed likely to live.

Experiment 6.—Inoculation by means of a platinum loop with a culture of *Staphylococcus albus*. There was prompt reaction on the second day, with iritis and exudation into the anterior chamber, which soon collected into masses above and below the pupil. On the eighth day some of this exudation was removed with forceps through a peripheral corneal incision and an attempt made to wash out the chamber, without much success, owing to the thick, tenacious character of the exudation. This produced no change in the eye, and on the eleventh day two iodoform rods were introduced into the chamber. The pannus already referred to had appeared on the seventh day. The iodoform was not visible after 24 hours, and no change in the eye being noted, two more rods were put in on the fourteenth day. Nineteenth day, pannus covered the whole cornea, but had become less dense. No other change. Twenty-second day, cornea much clearer. The exudation in the chamber was a central mass the shape of the crystalline lens and about two-thirds as large. Twenty-fifth day, exudation mass had settled a little towards the lower angle and pressed against the cornea, which bulged slightly. Forty-fourth day, exudation still shrinking. Seventy-seventh day, the cornea was diffusely cloudy. The exudation had become a little smaller, being then about 2 mm. in diameter. A few vessels ran in the cornea from above to the spot where the exudate touched the cornea. No fundus reflex.

Experiment 7.—Injection of a culture of staphylococcus producing but slight reaction, it was repeated on the following day with a positive result on the second day after the second injection. Two rods put in the eye on the eighth day. Tenth day, the exudation masses were smaller. Twelfth day, put two more rods in the eye. Seventeenth day, pannus completely covered the eye. The exudation masses in the anterior chamber appeared to be changed into connective tissue. They changed color from yellow to white, and small radiating bands appeared around them. Thirty-eighth day, the cornea was diffusely opaque and on its posterior surface and in the chamber elsewhere were a few small, white masses. The pupil is occluded, but the rabbit sees and is fat and well.

SUMMARY OF RESULTS.

Iodoform used in three cases of streptococcus infection. One failure, two successes.

Iodoform used in two cases of staphylococcus infection. Two successes.

One case of streptococcus infection not treated. The animal was destroyed at a time when sloughing of the cornea appeared imminent.

In addition to these experimental cases, I wish to record one clinical case in this connection:

Case 1.—H. D., a negro man, 58 years old, but who looked at least ten years older, was seen in February, 1902. He had a double cataract, mature in both eyes. The left eye had failed first, in 1897, the right in 1901. There was a very marked arcus senilis in both eyes, and in the left additional rounded opacities in the cornea down and in and down and out from the center. The eyes were otherwise normal; urine normal. The operation of extraction with iridectomy was done on the left eye on February 13 in the ward of a general hospital. The corneal section lay in the arcus. The operation was normal in every way and healing was prompt.

February 21 the right eye was operated on in the same way. The only difference in the two operations was that in the last eye (right) there was more soft cortical substance brushed off the lens in its delivery. On the morning of the third day the wound was closed and a slight mucopurulent conjunctivitis was present, but as this had also appeared in the other eye after the operation and did no harm, no special thought was given it. At 5:30 that afternoon I went to the hospital and found that, it being Sunday, the nurse had two wards to look after and had been detained in the other ward. My patient had removed the dressings from the eye and had rolled over on the pillow with the eye underneath. There was an increase in the amount of secretion from the eye and the wound showed marked infiltration of its edges. Iodoform was dusted into the eye and the organ was directed to be bathed in an antiseptic solution frequently. The next morning the discharge was more profuse, the edges of the wound were quite yellow and the anterior chamber near the wound contained a yellow exudation. Aqueous very cloudy and whole cornea slightly hazy. A culture showed *Staphylococcus albus*. At 2 p. m. the wound was reopened and an attempt made to introduce some iodoform powder into the chamber, no rods being available. The manipulation was very difficult, and only after prolonged efforts was an appreciable amount of the powder gotten into the eye. It did no good whatever, and was not repeated. The cornea became infiltrated and sloughed, the eye subsequently undergoing atrophy, and was enucleated a few months later.

This case occurred before I had undertaken these experiments. I now know with how much more ease the iodoform can be handled in the shape of the rods, and also the necessity of its early and repeated use.

In regard to the technic of the introduction of these rods into the eye, it presents no difficulties at all. A peripheral incision in the cornea is made and the rod caught at one end with any fine forceps and pushed into

the eye. It should enter the eye completely, leaving no part protruding. The gelatin softens very quickly on exposure to moisture, necessitating quick handling of it.

While the value of this procedure as a therapeutic measure does not seem to be brilliant, judging from the results of these experiments, we must not, in forming an opinion, lose sight of the almost hopeless nature of these cases under any other form of treatment. It appears to me to have a very distinct field of usefulness, and apparently has no possibilities for harm. To be of any value, it must be used early, probably on the first, certainly not later than the second day after infection, and should be repeated daily until positive improvement is manifest, or until its failure to control the condition is apparent. With small rods the dose should be three or four rods. It would be best to use at the same time such local antiseptic and general supporting measures as our experience has shown to possess some value.

DISCUSSION.

Dr. E. A. Shumway, Philadelphia—The subject of the treatment of infected wounds of the eyeballs is of very great importance, especially to those who live in manufacturing districts, where the number of accidents is large, and any method which will help us save such infected eyes and make the prognosis less grave should be welcomed as a step in advance in ophthalmic surgery. The use of iodoform within the eyeballs seems to have established itself firmly as a recognized mode of procedure. Ostwalt's experiments in 1897 showed that not only was iodoform well borne in the anterior chamber, but that it had a very decided action in checking the infectious process, especially when the lens was uninjured. Since then many favorable cases have been reported by Haab, Mayweg, Wüsterfeld and Goldzieher, from the introduction of the rods into the anterior chamber; and following the results of Ollendorff good results have been achieved by Schmidt, Wokenius, Haab and Römer by the use of the rods in the vitreous.

In this connection I would like to place on record two cases which were seen at the University Hospital in Philadelphia, this winter, in the service of Dr. Geo. E. de Schweinitz, to whose courtesy I am indebted for the privilege of reporting them.

Case 1.—J. B., aged 55, was sent to the hospital Oct. 10, 1902, for injury to the left eyeball, produced by a piece of flying metal, which struck the eye while he was working in a blacksmith shop, on the day previous. Examination showed a linear wound of the cornea, and commencing cataract. Under cocain anesthesia Sweet's magnet was applied to the eye, and almost immediately the lens was seen to bulge, and a piece of steel emerged from it into the anterior chamber. On enlarging the wound in the cornea, the foreign body was withdrawn from the eye without difficulty. Atropin was instilled, the eye bandaged and ice cold compresses were applied to the eye through the bandage. Calomel was given in doses of 1/6 gr. every hour. During the following night the pain was severe, and required hypodermics of morphia. Examination on the next day showed decided chemosis of the conjunctiva, injection of the eyeball, and bulging of the lens into the anterior chamber. The corneal wound was again opened, and following Randolph's advice, the opaque lens matter was evacuated, as far as possible, the chemotic conjunctiva freely incised, and the conjunctival sac dusted with powdered iodoform. On the following day (the fourth day after the accident) three sterilized iodoform rods were inserted by means of forceps into the anterior chamber. These rods were made by Shinn and Baer, local druggists, and measured 6 mm. in length, by 2 mm. by 1 mm. They were composed of 70 per cent. iodoform and 30 per cent. gelatin. The iced compresses were continued and atropin instilled regularly. The pain lessened at once after the evacuation of the lens, but three days later, as there was still considerable injection, two more rods were inserted. The eye then gradually quieted down, so that the man could be sent to his home October 28, eighteen days after admission, with a slightly flushed eye, which was beginning to shrink. He was seen at the hospital about four weeks later, and at this time the eye was commencing to assume a quadrate form, but was entirely quiet and caused no pain. With the strict injunction to report immediately to his doctor, if the fellow eye began to fail in any way, he was allowed to return home, with a sightless, somewhat shrunken eye.

Case 2.—B. B., aged 24, was struck in the right eye by a flying fragment of stone, which was chipped off by a chisel that he was using. The accident had occurred five days before, and in the interval he had been treated by his physician with iced compresses and instillations of atropin. The eye was decidedly injected, the cornea showed a yellowish infiltration of its lower one-half, and the anterior chamber was partly filled with a yellowish exudate. No details of the lens or iris could be made out. The magnet was applied to the eye, but no metallic foreign body could be detected. Iodoform was dusted into the conjunctival sac, atropin instilled and iced compresses were applied. As in Case 1, calomel was given every hour, and subsequently sodium salicylate, a dram daily, in divided doses. March 5, three days after admission, and eight days after the accident, there was still intense injection of the eyeball, infiltration of the cornea and anterior chamber with exudate, and bulging forward of the cataractous lens. The corneal wound was accordingly reopened at the clinic, the opaque lens matter and viscid exudate removed, so far as possible, and two rods of iodoform introduced into the anterior chamber. On the two succeeding nights the pain was very intense, necessitating the use of codeia and morphia, and the question of enucleation, or evisceration, was debated. But under the persistent use of iced compresses, atropin and salicylate of soda, the cyclitis gradually subsided. March 16, two weeks after admission, the inflammatory exudate had been absorbed except in the pupillary area slight cyclitis was still present, but there was no pain. The infectious process had been checked, and the patient was discharged eight days later, March 24. Since then he has been under observation at the clinic. The eyeball shows a decided flattening of its anterior portion, and a slight remaining ciliary flush. Vision is zero.

In other words, we had two badly infected wounds of the anterior part of the eyeball, in which the lens was injured, which, according to Ostwalt's experiments, is always a serious complication, as the swollen cortex seems to act as a good culture medium for the growth of the infectious organisms, in which the infectious process was checked, and the eye gradually quieted. The patients, workmen, were able to retain the eyeballs, which, although somewhat distorted and sightless, were painless, free from danger to the fellow eye, and better for them than a glass eye. It is, of course, difficult to say how much credit should be given to the iodoform, and we are too prone to ascribe all good results to some new method of treatment, but so many favorable reports have been made that I think we are justified in giving the method further trial.

Of the other methods which have been tried, subconjunctival injections of various drugs have proved of little value, experimentally at least. On the other hand, the use of intraocular galvano-cauterization, introduced by von Millingen in 1899, has, by virtue of the success reported by von Millingen, Roscher, Baumler and Zentmayer, established its claim of being of very great service in checking the infection by destroying the organisms in the lips of the wounds and along the back of the infiltrating process, and as there is no reason to prevent the use of both methods in the same patient, it seems to me we would secure the best results by cauterizing the wound and the infiltrated areas by means of the actual cautery, and then introducing the iodoform. The best way of introducing the iodoform is by means of the rods. It is almost impossible to prevent the powdered drug from being washed out of the anterior chamber, as the instrument used for this purpose is withdrawn. Pure compressed rods of iodoform would be best, but it is apparently impossible to make them without the use of some agglutinating material. It is of great importance, also, to evacuate the opaque lens cortex if the lens is injured,

and vigorous internal medication should not be neglected. Salicylate of sodium has proved of great value in large doses, and the recent remarkable results of Schirmer, who was able to show 60 per cent. of recoveries in cases of uveitis fibrinosa and 65 per cent. for uveitis purulenta by means of large doses of mercury, prove the remarkable efficacy of this line of treatment.

Dr. Frank Allport, Chicago—I have found considerable difficulty in securing the discs or rods. Professor Haab left me a bottle of them, which I have used, and I have been unable to have them properly made. I tried the Parke, Davis people and one or two other houses, but the results were always unsatisfactory. I am glad to have heard Dr. Shumway's discussion of this subject and his method of using the iodoform and gelatin.

Another difficulty that I have had is how to make these rods aseptic. As I understand it iodoform in itself is not necessarily aseptic and I have endeavored to render the discs and rods so in various ways, but have not been very successful, because the efforts to sterilize them has always resulted in making them difficult to handle. For instance, if you attempt to sterilize them in the sterilizer by means of heat, or more certainly if by steam, they become so limp that you can not handle them. So I have simply used them as I got them out of the bottle and have not noticed any ill effects; in fact, I have used them a number of times and have obtained very good results. Whether it was really due to the iodoform or not I could not say. In the cases where the iodoform discs seemed applicable I also, as a matter of precaution, followed the teachings of Dr. Gifford in giving heavy doses of salicylate of sodium, 1 gr. to every pound of weight, and I have had good results in the treatment of the cases where the iodoform seemed applicable, but as I say, whether due to the use of the iodoform or the salicylate of soda, or other treatment, I can not say. At all events my results have been good. I use the iodoform discs as a routine practice where I extract steel from the eye with the Haab magnet, which is the one I always use, whether there seems to be indication for it or not. After removing the steel I insert one of the iodoform discs and put the patient on heavy doses of salicylate of soda, and while I, of course, do not always get useful eyes (I sometimes get atrophied ones), I seldom have panophthalmitis, and I am inclined to attribute it to the iodoform or the salicylate of soda. I believe the iodoform to be a good method of treatment, but I have not confined myself altogether to the use of the discs; I have also used an emulsion of iodoform, injecting it by means of the Pannus syringe, and I think I have secured as good results with it as with the discs.

Dr. G. E. de Schweinitz, Philadelphia—The iodoform rods referred to by Dr. Shumway were made by Mr. Baer, a pharmacist of distinction in Philadelphia. Sterilization of the iodoform may be secured by washing the drug in a solution of bichlorid of mercury and subsequently drying it, but it does not make a great deal of difference when used in a highly infected eye whether the iodoform is sterilized in this or other manner.

My experience is too limited to give an opinion as to the value of this treatment, but I would like to emphasize Dr. Shumway's remarks as to the intense pain that was produced the night following their introduction. Whether this was due to some fault in my technic, or in the manufacture of the rods, I do not know, but the pain was certainly severe. The eyeballs thus treated gave evidence of approaching panophthalmitis. This dreaded result was averted; one resulting in partial phthisis bulbi, and the other in an adherent leucoma. Both patients were highly content at not having to submit to an enucleation.

Dr. J. H. Claiborne, Jr., New York—I take it that the purpose of these experiments was to combat any inflammation that might result after cataract extraction, or injury to the anterior part of the eye. In this connection I would like to make a preliminary report on some experiments which Dr. E. B. Coburn and myself have been conducting.

Following the recent instance, with which we are all familiar, of a gynecologic patient suffering with severe streptococcic infection, being treated with formalin, we made some experiments on the eyeballs of rabbits infected with streptococci. We injected a pure culture into the posterior chamber and conducted three experiments. In the first rabbit we injected, subsequently to the infection, formalin 1 to 5,000 into the vitreous humor; in the second the same solution into the capsule of Tenon; in the third no injection. The rabbit not treated recovered from the infection we had given it. The one injected in the capsule of Tenon recovered, while the one with injection in the vitreous chamber went straight to destruction. We then passed the streptococci through another growth, it being a well-known fact that the second growth is much more virulent than the first. All the eyes subsequently injected went straight to destruction. One thing proved was this, that streptococci can sometimes be introduced into the eye permanently without any bad effect, which fact accounts for the independent recovery of some of the infected cases we see.

In order that our experiments might be in the line of infections following operations, we took an infected rusty nail and thrust it into the anterior chamber and ciliary body. These cases all went to destruction at once. We then tried injections of formalin 1 to 500, but with no effect.

These experiments, it seems to me, are most commendable because if there is one bugbear for ophthalmologists it is the secondary inflammations following cataract extractions. I never perform a cataract extraction that I do not have cold chills for a day or two following. So, if any light can be thrown on the subject it is to be commended. The results shown in these reports are not very brilliant, but they are in the line of investigation. I think that some other agent should be tried, and would suggest the use of formalin 1 to 500, or 250, as soon as the symptoms of suppuration commence.

Dr. Albert B. Hale, Chicago—One remark was made that I do not like to see go unchallenged; that is, that it would be well to combine the use of the galvano-cautery with the insertion of the iodoform rods. The idea in using the rods is to preserve the eyeball, while the result of the cautery is destruction absolutely. We know how completely it destroys tissue and what a scar results. If we use the cautery we destroy a large part of the area which we want to heal normally. If we can get success with the rods the cornea is normal and clear.

I am not quite convinced myself of the good results obtained when vision is nothing. It is only a surgical experiment that has resulted with surgical success, but leaves the patient no better off, and time would have been gained by enucleating the eyeball at once. Of course it may go on for some years without causing trouble, but I am in favor of removing the ball when it is of no use to the individual.

Dr. E. C. Ellett, Memphis—The rods I made use of were 50 per cent. iodoform in gelatin. That strength, of course, was arbitrary; I had no special reason for making them that way, but it makes an easy rod to handle. The attempts at sterilization were by heat. The mixture of iodoform and gelatin was heated to a sufficient degree to sterilize, and then poured out on sterile tin plates, and when cool cut and the rods made. These were put into sterile containers and used without further preparation.

CONDITION OF THE ENDOMETRIUM IN CASES OF UTERINE MYOMATA.*

THOMAS S. CULLEN, M.B.
BALTIMORE.

CERVIX.

As a rule the cervical mucosa shows no change. Occasionally, however, cervical polypi are present or the cervical glands may be moderately or markedly dilated. In rare instances true cervical erosion, in other words an ulceration of the cervix, exists, and now and then squamous-cell carcinoma or adenocarcinoma of the cervix

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

may be associated with myomata. Where the cervix is much lengthened out the glands are often unraveled. We then note the squamous epithelium of the cervix alternating with that of the unfolded glands.

BODY.

Endometritis is occasionally found; when present it is almost invariably associated with inflammatory changes in the adnexa.

Tuberculosis is not uncommon, but while sometimes occurring independently, is usually associated with similar processes in the fallopian tubes.

Finger-like or dome-like projections from the mucosa have been seen from time to time, and also other pictures more or less suggestive of a malignant change.

Adenocarcinoma of the body of the uterus is quite frequently associated with myomata, as we have noted elsewhere. In the majority of cases it was not suspected.

While any of the foregoing conditions may exist, yet in nearly all instances the changes present are entirely mechanical. If myomata are subperitoneal or intraligamentary, the mucosa is usually normal, provided the tubes are unaltered. When a nodule impinges on the cavity the mucosa over the most prominent part becomes stretched and thinned out. This progresses until eventually there is nothing but the surface epithelium covering the nodule. While this atrophy is increasing the mucosa in the depressions at the sides remains unaltered or becomes thicker. This thickening is occasionally due to simple gland hypertrophy. Portions of the mucosa are often mechanically forced out into the cavity, producing polypi. With the distortion of the mucosa the glands sometimes become blocked, producing small cystic dilatations. The glands of the mucosa are sometimes much dilated, and not infrequently there is considerable edema. When the myoma becomes entirely submucous it is usually covered by a thin layer of mucosa, but in a few instances we have seen a sloughing cavity in the myoma opening directly into the uterine cavity. Now and then a submucous myoma from the posterior wall will blend with the similar nodule in the anterior wall, obliterating the mucosa entirely over a given area.

From an examination of a great many specimens we can lay down the general rule that where the fallopian tubes are normal and where no sloughing submucous myoma is present, that the uterine mucosa will be perfectly normal or show simple mechanical changes. The import to the surgeon is that where such favorable conditions are present he can do a myomectomy, opening, if necessary, a large part of the uterine cavity with little danger of infection. On the other hand, if the tubes be adherent, or a sloughing submucous myoma be present, complete removal of the uterus is indicated, the sloughing submucous nodule, of course, being removed some time prior to performing the hysterectomy.

These results are based on the gross or histologic examination of nearly one thousand cases.

Properties of Hydrogen Peroxid.—A good make of hydrogen dioxid is an efficient disinfectant and the best deodorant known. It will even banish the odor of putrid standing urine. It also arrests parenchymatous hemorrhage, and its efficacy in cleaning out wounds and loosening adherent dressings is bringing it more and more into use. It bleaches hairs, banishes freckles and is the only effective antidote known for hydrocyanic acid. It is also an excellent cleansing material for instruments, checking bacterial development.—*Allg. Med. Ct.-Ztg.*, lxxii, p. 195.

THE ILL-HEALTH OF RICHARD WAGNER.

GEORGE M. GOULD, M.D.
PHILADELPHIA.

(*Concluded from p. 297.*)

By no means is he out of the wood with his nerves, for he has to send apologies through Uhlig to another correspondent next day for not answering at once: "That sort of letter always takes a deal out of me." Not a word about the poem; nor in that to Liszt on the morrow, October 13.

"Nothing further to-day. Used up as I am, it would only be lame. . . . Your old tormentor, Richard Wagner." On the 14th, just three days after the "forced pause" has been made in his poem, the migraine seems to have renewed its attack: "I wanted to work, but felt so ill that I had to pass the whole forenoon on the divan, half asleep, half awake. There'll have to be an alteration in me."

That I have been unable to work to-day has terribly depressed me! How I should have liked a couple of days' outing—but the weather is too vile—regular 2d December!"

So Rheingold is half finished, apparently by October 10. That half has taken something like four weeks to versify, or as long as the whole of die Walküre last June, owing to its author's wretched health compelling him to work in snippets. And it must have been followed by another acute relapse, since not a line stands written to any of his correspondents between the 14th of October and the end of that month. November 1 we again hear of the poem at last, in terms that suggest its having been resumed about a week previously: "You'll get but a half a dozen lines to-day, dear friend (U.). After some interruption (through being unwell) I have arrived at devoting all my power of application exclusively to the completion of 'Rheingold,' and shall not stop myself to write long letters before I'm through with it. That, however, will be during the course of this week, at the end of which I therefore promise you a proper letter." November, 1852, began with Monday; by the 3d or 4th, then, "Das Rheingold" was finished as to its verses; for Uhlig is told on the 10th, "The middle of last week I completed my work, very much exhausted." Scarcely more than ten days can this second half of Rheingold have taken him, so that he must have doubled his "little hour" of late. As a matter of fact, the next letter to Uhlig will satisfy our minutest curiosity even on that point: "The postman comes at 11 every morning; I usually work from 9 o'clock until that hour, and therefore am already somewhat tired and in need of rest when my letters arrive. This places me in the alternative of either not answering at all or doing it as briefly as possible. If I put it off it's precisely the same next day, unless I stop my work entirely for one morning as happens when I mean to write a longish letter. From noon till bedtime I never write another line, except in the most pressing emergency."

When the poems of "Young Siegfried" and the "Walküre" were finished we found their author giving vent to the utmost joy; there is nothing of the kind to celebrate the consummation of the Rheingold poem. Partly due to the fateful lesson of the work itself, the greater share of this lack of elation must be assigned to the same cause that had impeded the poem's progress: excessive nerve fatigue. The letter that announces the event to Uhlig—and a very long letter it is, as a rest is being taken—for the most part consists of reflection on death and diet: "Let us be reasonable, dear friend, and recognize in utmost calm that every one of us bears within himself the genetic seeds of his own death, and that the only question is how to stave off that specific death as long as possible. With myself, e. g., everything tends to death through nerve consumption. . . . So long as I still have an object in life I wish to keep death from my throat, and for that reason adopt all feasible expedients to preserve myself. I purposely avoid all over-exertion, step out of the way of all over-excitement as much as possible, try to regulate my feeding and digestion, and aim above all at the utmost comfort, repose, agreeable impressions—so far as I can. I'm assured by many that I still may jog along awhile if I strictly observe this diet, and

analogies are making it credible even to myself. . . . Simple foodstuffs are not for such as you and me; we need the complex substances that offer the utmost nourishment with the smallest demand on the power of digestion. Our rule should be to eat often, little and good, at the same time to avoid all great exertion, even in bodily movements, but be careful for comfort and agreeable rest." It is the valetudinarian's gospel; but, when the invalid happens to have such an "object in life" before him as the composition of a "Ring des Nibelungen," it becomes his absolute duty to take care of himself for sake of the world.

The announcement of the previous day to Liszt (November 9) is more plainly despondent in tone, shadowed as it is by the failure of the Berlin scheme for Tannhäuser, the history of which precedes it in this letter. "With myself things are going from bad to worse each day; 'tis an indescribably good-for-nothing life I'm living! Of actual enjoyment of life I know absolutely nothing; to me the 'pleasure of life, of love' is purely a matter of imagination, not of experience. So my heart has had to pass into my brain, and my life to become a mere artificial one; only as 'artist' can I still live; into the artist has my whole 'man' been resolved.

"If I take account of my wretched state now normal to me, I can not but deem my nerves ruined; strange to say, however, these nerves do me the most wonderful service when put to it when sufficiently fine incentives come to me; then I have a clearness of vision, a sense of pleasure in perceiving and creating such as I never knew before. Ought I to call my nerves ruined then? I can not. Only, I see that—in the way my nature has developed—its normal state is exaltation, whereas the ordinary calm is abnormal to it."[2] 1852.

The same complaint of nerve fatigue that formed a running accompaniment to the Rheingold poem ushers in the revision of the two Siegfrieds: "I must stop; my head's getting bad." November, 1852.

Uninterrupted work has again strongly affected me, and the nerves of my brain are so overwrought that even these few lines put me in a state of violent excitement, wherefore I must ask you not to be angry if I make them very short. June, 1852.

I feel that I am still capable of doing good things, but only by keeping very strict diet, and especially by frequently interrupting my work and entirely diverting my thoughts before going on again. *Do.*

The "Valkyrie," the poem of which I finished on July 1, I wrote in four weeks; if I had spent eight weeks over it I should now feel better. In future I must adopt this course. *Do.*

Unfortunately, I can not reply to your letter as I should like to do; the nerves of my brain are once more in a state of great suffering, and for some time I ought to give up all reading and writing, I might say, all mental existence. Even the shortest letter wearies me terribly. . . . I only wish to explain to you why it is that to-day I must limit my communication to stating briefly what is absolutely necessary. . . . The work has been a perfect torture to me. This eternal communication by letter and print is terrible to me. September, 1852.

My nerves are not in the best condition, but I have begun again to work at my poem for an hour or so every day. October, 1852.

I am going from bad to worse every day, and lead an indescribably worthless life. . . . Perhaps you will soon be rid of me. November, 1852.

My terrible melancholy. January, 1853.

In case I should die during the work. February, 1853.

How long I shall endure this terrible joylessness I can not tell. About the middle of last month I was on the point of succumbing, and thought that I should soon have to follow my poor Uhlig. I was persuaded to call in a doctor, and he, a careful, considerate and conscientious man, takes much trouble with me. He visits me nearly every other day, and I can not but approve of his treatment. Certain it is that if I do not recover it will not be his fault. . . . For me there is no salvation but *death*. Would that it found me in a storm at sea, not on a sick bed. February 11, 1853.

I can only live in extremes—great activity and excitement and—most perfect calm. March 4, 1853.

My nights are mostly sleepless. March, 1853.

Whether the cure has been of any use to me the future must show, but on the whole I am not inclined to repeat it. At St. Moritz, July, 1853.

The foolish man wants to hear something from me about his book, but as soon as I bend my head a little towards theory the nerves of my brain begin to ache violently and I feel quite ill. *Do.*

Truly writing is a misery, and men of our sort should not write at all. Aug. 7, 1853.

I am in a miserable condition, and have great difficulty in persuading myself that it must go on like this, and that would it not really be more moral to put an end to this disgraceful kind of life. . . . To cure my sick brain the doctor has prevailed on me to give up taking snuff altogether; for the last six days I have not taken a single pinch, which only he can appreciate who is himself as passionate a snuff-taker as I was. Only now I begin to perceive that snuff was the solitary real enjoyment that I had occasionally, and now I give that up, too. August, 1853.

I am back again in Zurich, unwell, low-spirited, ready to die. . . . At Genoa I became ill, etc. September, 1853.

I have many things to tell you, but my head is burning. There is something wrong with me; and sometimes with lightning-like rapidity the thought flashes through me that it would be better after all if I died. December, 1853.

The Rheingold is done, but I also am done for. January, 1854.

I went to this music (Rheingold) with so much faith, so much joy; and with a true fury of despair I continued, and have at last finished it. *Do.*

With my terrible care my violent nervous disorder has also returned. *Do.*

. . this having to make a clean copy kills me. . . . the continual writing tires me to such an extent that I feel quite ill and lose the inclination for real work. March, 1854.

This dislike of work (composition) is the worst feature of all. I feel as if with it eternal night were closing around me. May, 1855.

My frequent nervous headaches. Letter to Wesedonck from London, 1855.

My mental disharmony is indescribable; sometimes I stare at my paper for days together,[3] without remembrance, or thought, or liking for my work. Letter to Liszt, July, 1855.

After much trouble the first half of the Valkyrie, including a clean copy, has been finished. . . . For the last week indisposition has prevented me from doing anything, and if this goes on I almost doubt whether I shall be able to finish this work from the sketches. *Do.*

I am making a tentative effort to rise from the sick bed on which I have lain again exactly three weeks . . . I have suffered from continual attacks of erysipelas of the face. December, 1855.

I am again, or rather still, unwell and incapable of anything. January, 1856.

I am continually at war with my health and fear a relapse at any time. *Do.*

I am waiting to see what my health will do; my doctor wants to send me to some watering-place, but to this I will not and can not agree. During 1856.

Again on a sick bed. To-day I am scarcely recovered, and fear another relapse. . . If I could only be well again! . . Another attack of erysipelas. . . This abominable illness has brought me very low. . . The slightest disorder of my stomach immediately affects my complaint. *Do.*

In that terrible month of May I was able only to look at your scores with a tired eye, and as through dark clouds. *Do.*

2. Compare this with the experience of Carlyle (v, p. 70, *Biographic Clinics*), who in the same way and from the same reason had to work "in a red-hot element," "with his heart's blood in a state of fevered tension," etc.

3. Compare similar expression by Carlyle.

My only care now is the perfect recovery of my health. *Do.*

God knows I castigate my flesh by this cure . . . placed myself under Dr. Vaillant who conducts a hydropathic establishment here. . . . I feel sure of being completely cured of my ailment, which, after all, was caused by nervousness. July, 1856.

During my cure I must not think of doing any work. *Do.*

My catarrh has developed so that I may hope it will rid me of my usual winter illness. My health, too, is once more so bad that for ten days after I had finished the sketch for the first act of Siegfried I was literally not able to write a single bar without being driven away from my work by a most alarming headache. Every morning I sit down, stare at the paper, and am glad enough when I get as far as reading Walter Scott. The fact is I have once more overtaxed myself, and how am I to recover my strength? With Rheingold I got on well enough but the Valkyrie caused me much pain. At present my nervous system resembles a pianoforte very much out of tune. January, 1857.

Imagine that for a week and a half I have not been able to move from my chair. This illness was just what was required to finish me up. I had just resumed my work a little after a gastric and nervous indisposition, when I was obliged to give in again. December, 1858.

The weather is bad; I am absolutely alone, and seldom in the right mood for work. So I drag on amidst mists and moods. 1858.

My health still gives me much trouble. 1859.

My health is ruined for want of life and action. *Do.*

The last act of this child of sorrow (Tristan) is now on the verge of "to be or not to be"; a slight pressure of some spring of the vulgar fate, at whose mercy I am, might kill this child at the very moment of its birth. Everything with me depends now upon the turning of a hand; there may be a way, and there may be a stoppage, for I, my Franz, am in a bad way. . . . How miserably weak I feel as a musician. I know in my heart that I am an absolute blunderer. You ought to watch me when I am at it; now thinking "it must do after all," then going to the piano to puzzle out some wretched rubbish, and giving it up in a state of idiocy. 1859.

I feel as if I should break down in sight of the goal. Once at least every day I look at my book (Tristan) with a right good will, but my head is waste, my heart empty, and I stare at the mist and the rain clouds which, ever since I have been here, have debarred me even from the chance of shaking up my stagnant blood by pleasant exertions. . . work alone is to help me, but who is to help me to the possibility of work? 1859.

I have been severely ill these four weeks and my recovery is scarcely noticeable. I am still extremely weak. . . . I begin to perspire, and can write no more. *Do.*

I cannot write at greater length . . because I must absolutely conclude these lines. *Do.*

I am very slowly regaining my strength. What impedes my recovery, and indeed makes it impossible for the present, are the extraordinary exertions and excitements to which I have to expose my health, which is gradually coming back to me. . . . The proofs of Rheingold, which Messrs. Schott would have liked so much to have published at Christmas, have been lying on my table for seven weeks without my being able to make any progress with them. Letter to Liszt, 1860.

I seek rest and happiness no longer, but only breathing space for new labors, from which I reap the least enjoyment. 1860. Letters to M. v. M.

His exertions brought on a serious illness which threatened to develop into brain fever. Ellis, 1860.

I am doing my best, at the doctor's orders, with all kinds of strengthening diet. 1860. Letters to Wesedonck.

Through my weeks of illness. *Do.*

A night slept through from 1 to 8 a. m., is an ideal happiness to me which I only taste as an utter rarity. 1861. *Do.*

. . . traveled to the south of France by his doctor's advice. 1865. *Do.*

A doctor, whom I have consulted, recommends me Cannes. 1864. Letters to E. W.

I was hindered by terrible sickness from continuing my journey that day. *Do.* 1864.

"People often call me irascible, when I am simply ill," he used to say. (Fink.)

From 1866 to 1872 at Triebschen, Wagner displayed a creative activity which was simply incredible. (Chamberlain.)

Happiness has no history. The six years at Triebschen were the happiest of his whole life. *Do.*

Truly all our politics, diplomacy, ambition, feebleness, science—unfortunately, too, all our modern art—all these parasitic growths upon our life have no other soil upon which they flourish than our ruined stomachs. Letter to Liszt. (He seems to have thought vegetarianism "the keystone of regeneration.") We must abstain from meat and alcoholic drinks. Only adopted late in life.

I shall devote next summer to nothing but the possible recruiting of my health—for which on account of the wearing and increasing pains in my abdomen, I think of taking a very protracted course of waters at Marienbad and so on. If I find myself restored to health, etc. . . . In one of my perpetually sleepless nights I have tried to gain a little ease, etc. Letters to Heckel, 1876 (p. 99).

In 1878 a medical examination showed amyloid degeneration of the liver, spleen and kidneys. (Ellis.)

I am at the commencement of a course of waters, which may be very prolonged, etc. He had "a serious illness" in 1880. (Serious organic diseases at this time set in.) *Do.* p. 118, 1879.

Only to-day do I write you, as this mournful business had to be postponed because my health is such that my dear wife was afraid even to impart to me the news of the sudden death of your father. *Do.* p. 127, 1882.

During the last few months there was much dyspnea, especially after meals, but he was also busy writing several hours every morning. (Ellis.)

He died February 13, 1882.

The necropsy showed a much dilated stomach, internal inguinal hernia, much dilated heart, with fatty degeneration. Death occurred directly from rupture of the right ventricle.[4]

Headache, "sick headache," "dyspepsia," "nervousness," melancholy, insomnia, indescribable suffering—these were some of the more prominent symptoms that, in various mixtures, rendered so miserable the lives of DeQuincey, Carlyle, Darwin, Huxley, Browning, Whittier, Spencer and Parkman. Some had some of the symptoms all of the time, some had all of them some of the time. Wagner had all of them all of the time. All of them found these symptoms exactly proportioned to the amount of reading and writing that was attempted, and when the eyes were driven to their unphysiologic function the symptoms increased in intensity until life itself was threatened either by the disease or by the despair of the patient. Darwin and Wagner kept up the sad belief in the therapeutic uses of hydropathy all their lives. Carlyle and Parkman tried it, but soon perceived the folly of it. Every one of the eight learned that the

4. The letters to Pusinelli, published in the Bayreuther Blätter in 1902, have been kindly sent me by Mr. Ellis. They bear dates from 1843 to 1878. They begin with "I have headache," and continue with complaints of bad weather and bad health; of growing old and loss of joy (aged 33); of increase of illness; working at composition with consequent frightful suffering; with prayer for peace, peace; moans at the uselessness of life; regrets at inability to get a good photograph; sleeplessness. Baths and douches drive him nearly crazy. There is longing for his natural joyfulness; reiteration of physical and mental exhaustion; the thought of suicide; emphasis of his irritability, and of his inability to write another line, etc.

An illuminative and instructive excerpt is this: "As regards my health, I appear to those who should know as an instance of a peculiar order of men destined to a long life of work. I am very sensitive and irritable, quickly becoming feverish and perspiring, but never really ill and recovering from indisposition so soon that I seem ridiculous."

This was in 1870, when presbyopia and the release from the use of his eyes brought happiness and peace. Thenceforth there is no complaint of functional disease.

only cure or relief to be found consisted in stopping reading and writing, i. e., in non-use of the eyes at near range, and in out-of-door exercise.[5] In addition to all the affections mentioned, Wagner had the mercuric artistic temperament, endured the bitterest mental anguish from non-recognition and hate of his musical work, and he was poor. He also suffered all his life from an intercurrent affection, erysipelas, which is a disease dependent on denutrition. There can be nothing in medicine more certain than that eye-strain causes denutrition; and nothing more certain than that Wagner had terrible eye-strain.

It should be noted that Wagner was a "delicate boy," "a pale, slim little chap," needing to "pick up strength," not profiting by instruction, liking others to read to him, "preferred rambling," "roaming about the country," an excitable and fitful sleeper, shouting and talking in his sleep, etc. But the intellectual and keen mind soon realized the sense of responsibility, and the boy picks up his school work equal to the best from 9 to 14, but at 25 his features have "the look of wanness and suffering." All of which is an excellent description of eye-strain in children, and can be duplicated from oculists' case records many times.

At about 30 years of age an excess of writing work overtaxes his nerves so much that he has "often sat down and wept for a quarter of an hour at a stretch," and he is a constant victim of a feeble stomach. At this time an extreme amount of work with his pen brought on the idea of sudden death which under the same circumstances reappeared many times during his life, and seemed to drive him to suicide. The doctors warned him against work, said, "determination of blood to the head," ordered leaves of absence for three months, etc.[6]

With each increment of added accommodation-failure things go from bad to worse every year until at the age of 35 he feels "too old" for undertaking his greatest art-work. Depression and suffering, "brokendownness," always follow near-work, and especially so in winter, his "mortal enemy," when vitality was always lowered, because there was more confinement in the house, and hence more reading and writing. A hundred statements grow ever clearer and clearer that writing and reading are becoming more and more impossible, produce greater and greater suffering, and that after each opera, poem, or literary work the ill-health is more tragical. He can not even undertake "to make a copy," music-writing is "natural and easy," and yet at the very beginning of such labor he is warned that he will undermine his health. Finally "the nerves of his brain are so overwrought that the writing is reduced to two hours a day, instead of five or six as formerly, and the writing of a few lines of a letter "sets him in violent commotion." As all good oculists instruct their patients, so Wagner found by experience he had often frequently to interrupt even his two hours a day of eye-work. Every job of composition or writing "takes much out of him," and he has "to rest it off." Headache, sleeplessness, the "working by spurts," "with long interruptions," a hundred such expressions occur, and the fear of death, the longing for it, or the resolve to seek it, is constantly appearing. One could gather hundreds of such expressions as the following: "If my head were but better"; "I shall go mad"; "the sharp knife cutting into the nerve of my brain"; "feverishly tired in all my limbs"; "even this letter almost knocks me down"; "I *mustn't* write, because I can't"; "my head is nigh bursting"; "every letter knocks me terribly up"; "the nerves of my brain are so racked that I have had to give up all writing and reading for a while"; "I even work a *little* hour a day now"; "a short hour a day now off and on"; "I shall shortly go crazy"; "letter writing I am now convinced, once for all, severely taxes me, and you, therefore, may flatter yourself if I manage to fill even this sheet of paper"; "completed my work very much exhausted"; "from noon till bedtime I never wrote another line"; writing a "longish letter prevents all other work that day"; "I must stop, my head's getting bad"; "even these few lines put me in a state of violent excitement"; "I ought to give up all reading and writing"; "even the shortest letter wearies me terribly"; "my work has been a perfect torture to me"; "this eternal communication by letter and print is terrible to me"; "my terrible melancholy"; "my nights are mostly sleepless"; "as soon as I bend my head toward theory the nerves of my brain begin to ache violently, and I feel quite ill"; "truly, writing is misery, and men of our sort should not write at all"; "the Rheingold is done, but I am also done for"; "this having to make a clear copy kills me"; " I begin to perspire and can write no more"; "the proofs are lying on my table for seven weeks"; "farewell, I must stretch myself full length on the divan and close my eyes." One may excuse this poor patient for not recognizing the simplest conclusion that the eyes were at the bottom of all this suffering. One may with difficulty excuse the medical men of his day. But there is no excuse for the most cruel of crimes—the brutal obstinacy which to-day makes a few ultra-conservative physicians, and even some careless oculists, deny that such symptoms in thousands of patients are due to eye-strain, and are daily cured by its correction.

Even to-day men are wet-packed, as Wagner and Darwin were all their lives, for astigmatism. The silly superstition that there is any mysterious virtue in cold water has been, and is still, filling quacks' pockets and exhausting the vitality of numberless patients. Let one with open mind read the hydropathic histories of Darwin and Wagner, and not have his gorge rise with indig-

5. The alert-minded reader will find in his biographic reading constant proofs of the rôle of eyestrain which have hitherto escaped notice. For instance, of Adolph, the nephew of Richard Wagner, a man devoted to literary work, I find the following suggestive paragraph: "His bodily strength now commencing to fail, with the advent of maladies brought on by the sedentariness of his occupation, Adolf resumed his favorite exercise of old, long walks, which he did not abandon until a year or so before his death." "For a year and a half or more I suffered from excruciating headaches; neither the allopathic nor the homeopathic doctors, for all their promises, helped me in the slightest. Spring came; I tore myself from my work, said good-bye to thinking and trudged for several miles a day—and still am doing it in November, whenever the weather is not wet or boggy."

Perhaps a more striking case is that of Beethoven. At the age of 53, when presbyopic strain is usually at its height, says Mr. Ellis: From April to mid-August, 1823, the period in which the Ninth Symphony was actually written, Beethoven was a martyr to (neuralgic?) pain in his eyes, for the only time in his life. Nor was that all. August 16 he gives his nephew a catalogue of his various ailments, which are such that he fears "they will soon cut short the thread of life, or wear it gradually away." A few days afterwards he writes his Archduke Rudolf, from Baden, "I came here on the 13th, very ill, but am better now. I had recently been attacked again with my catarrhal affection; besides that my bowels are in the most wretched condition, and then also the trouble with my eyes; in brief, my organization was entirely shattered" (see Die Musik, 1902, pp. 1155-60). Save for the special symptom of the eyes, one might have mistaken it for Wagner writing to Uhlig.

6. As I write this a patient comes in bright and happy and healthy who two months ago was the absolute reverse of these things, and whose life had been made as miserable as that of Wagner, and from the same cause. In his melancholy and suffering his greatest danger had been suicide. Great nerve specialists had drugged him to stupor, or had "rested" him nearly to death. Luckily he escaped the hydropathist and Christian Scientists. On this same day I also receive bitter criticism from a great ophthalmic surgeon that I am an exaggerator and hobby-rider. A great rest-cure man does not even acknowledge the receipt of a complimentary copy of "Biographic Clinics." And so on.

nation! The sole good done by this nonsense to offset the enormous evil was that while shivering in dripping sheets the poor eyes and brain could not be doing reading and writing. Hence the little seeming good, the raised hopes—and the succeeding despair—when ocular strain was again resumed.

Wagner's clearest symptom was "sick headache"; migraine, megrim, hemicrania, nervous headache, or bilious headache are other names for this terrible affection. It causes a large number of other symptoms, and is itself of an infinitely varied type, according to the kind of near-work required, and the kind of organism of the patient. I have had thousands of patients with this disease, and 99 out of 100 were cured by spectacles alone. That sick headaches often disappear at the age of 50 to 60 is due solely to the fact that presbyopia makes eye-strain impossible. That the wrecked nervous system may sometimes go on exhibiting the symptoms after the exciting and direct cause has ceased, is a truism not only of medicine, but of common sense. "From 1871 onward he had an immense amount of business to transact," writes Mr. Ellis to me, "in connection with the building of the Bayreuth theater, etc., but of specific complaint of headache I nowhere find a trace in the later years." All the symptoms of Wagner's functional diseases ended with the establishment of presbyopia. The sick headaches, melancholy, fear of death, resolve to commit suicide, nervousness, insomnia, etc., and then, not because the King of Bavaria came to the rescue of this greatest of musical geniuses, not because the bad wife went and the good one came, not because success and popularity arrived; but it was because, his wife acting as an amanuensis, etc., he was not driven to the maddening eye-labor, and because presbyopia prevented the suffering which was the result of the least of such labor. One eye at last went out of function, and this helped also to establish some relief.

In Wagner's passport he is described as "wearing glasses." Outside of that simple statement no one ever seems to have seen him doing so, or spoken of the fact.[7] Mr Ellis has proof that seems to him pretty good that he did not wear them. It is of no consequence whatever. Any spectacles he could get would have neutralized his eye-strain. Were he living to-day he would in all probability not find any oculist or physician in Germany that would help him or care to help him in the one possible and effective way. There are a hundred oculists, nerve specialists and general physicians, even in the United States, who would smile scornfully at the idea that a patient having Wagner's symptoms could be cured by the correction of his ametropia. Fortunately there are hundreds of others who know the truth, and better, who practice it.

All through the latter part of Wagner's life he had one symptom, one of those which physicians call "objective," one that is alluded to, so far as I know, by no written word. In speaking to a great musician who knew Wagner, I mentioned this symptom, when he broke in with, "Of course! I had often observed the fact, but thought nothing of it." This symptom, which all of his physicians also ignored, comes out in most of the later photographs and the portraits, especially in those of Lenbach, the realistic painter. The left eye is turned out and up. Consult the portraits herewith reproduced. Some American oculists call this defect "hyperexophoria." In the effort to drag the eyelid away from and above the pupil of this eye the forehead is arched and wrinkled in concentric curves—an appearance noticed in many such patients. In the pictures in early life this combination of heterophoria and strabismus is not shown—because it did not exist. It had been overcome by strain, if it existed, and the strain had produced its effect.[8] Some of the later photographs do not show the outward and upward turning of the eye, a fact that demonstrates the temporary ability to overcome it by intense effort of fixation or concentration of the attention. This turning of the left eye upward and outward is, as oculists know, a result of ametropia, and especially of astigmatism and anisometropia. It was a relief of eye-strain, an effect rather than a cause of it—a fact that the "graduated tenotomists," the cutters and snippers of eye-muscles, forget.

A bungling newspaper headline of a review was "The Eye of Genius"—as if geniuses had a peculiar sort of eye-defect. The geniuses are few, the slaves of civilization millions. Even Wagner and Carlyle and DeQuincey, as poor as they were, could stop near-range ocular work when they were compelled to do so, or limit it to "a little hour" a day. Sewing women, typewriters, clerks, many students, teachers, all poor handicraftsmen and women can not do so. They must work eight or ten hours every day, and all days, with the same ocular defects as the "geniuses." The tragedies to them are therefore greater than to the geniuses. There is no greater cruelty, no greater crime against humanity, than this of non-recognition and scorn of eye-strain.

This evidence presented by the portrait painter and the photographer of Wagner would not be needed by the expert oculist to prove the fact of the cause of his lifetime of awful misery. It adds the demonstration needed to convince general physicians and intelligent laymen. Many thousands of such non-medical persons who have been cured of appalling sufferings like those endured by Wagner would not need such a proof. The mere reading of the list of quotations I have gathered would make them shudder to think of their own past experience. Multitudes of others still await the finger of a divine science on their eyes. But that touch must first come to the eyes of the physicians, too many of them still blind by prejudice and tradition.

7. What Wagner thought of spectacles may be gathered from a sentence in a letter to Friederic Nietsche, written in 1874: "Overbeck delights me, because so far he has been able to do without glasses." Of course, his contempt was justifiable, and would be so to-day were he living in Germany.

7. Even in the later photographs the ocular defect is not always shown, chiefly probably because he was able by intense effort to overcome it and secure "binocular fixation." In a letter to Dr. Pusinelli Wagner says that the constraint and mechanical preparation for being photographed rendered it very difficult to procure a faithful likeness of his "so changeable expression." Whether "fixing" with both eyes or with but one would make a great difference in the expression. The vertical wrinkles between the eyes are also proof of eyestrain.

Implantation of Adipose Tissue After Evisceration of the Eye.—M. Uribe Troncoso of Medico, editor in chief of the *Anales de Oftalmologia*, publishes in No. 11, Vol. IV, his application of the method of autoprothesis after evisceration suggested in 1901 by Barraquer of Barcelona, Spain. The latter reported a single case thus treated, but has not published the remote results. After evisceration he introduced into the cavity left a piece of adipose tissue slightly smaller than the missing eyeball. Troncoso performed the same operation on a nine-months' babe whose purulent ophthalmia neonatorum had been neglected. The piece of adipose tissue was taken from the buttocks and had healed into place without diminishing materially in size when the child was last seen, nearly two months later. He much prefers this autoprothesis to the use of paraffin or any other foreign body. Less suturing is required to hold it in place than a glass prothesis.

Clinical Reports.

A CASE OF OSTEOMALACIA (?).

JAMES R. MONTGOMERY, M.D.
BUCKHORN, PA.

Mrs. A. N. was a large, well-developed woman with good family history. Both parents died of old age. There is no specific history nor any reason to suspect any. She has never borne any children. I have been her physician since 1882 and she had no serious illness in that time until 1888, when she suffered from a severe attack of sciatica which lasted about six months.

Ten years later, in 1898, she fell on an icy walk, fracturing the right femur and the left humerus. Both bones united in the usual time and with good results. At this time I noticed that she was becoming decidedly stooped, but attached little importance to it.

Nine months later, while walking across the room she either tripped, or her leg gave away, and a fracture resulted at the site of the former one. This was set in the same manner as the previous one, but for three months the bones did not unite. At this time, suspecting softening, I put her on powdered bone and in six weeks firm union had taken place, though with considerable shortening, but owing to the weakness, the pain

on motion, and above all, the apathetic mental condition of the patient, she remained bedridden.

Soon after this the family removed to Bloomsburg and I lost sight of her.

Three years later, in March, 1902, I was requested to see her. At this time I found much emaciation of the upper part of the body and of the arms and a great increase in the size of the abdomen, pelvis and especially of both thighs. The left thigh was somewhat shortened and very painful. There was apparently total absence of the shaft of the femur in this limb. The mental deterioration was very marked. I prescribed acetanilid for the relief of the pain.

Several weeks ago Drs. W. M. Rebu and F. W. Redeker and I examined her. Her condition was pitiable. Her mental condition was one of extreme dementia. There was great emaciation of the upper half of the body. Her voice had that peculiar tone sometimes noticed in syphilis of the nose and throat. The bodies of the last three or four cervical, and nearly all the dorsal, vertebræ are apparently gone, seemingly, causing that part of the spinal column to arch back in a huge shapeless tumor. The abdomen is much enlarged and this, in connection with the emaciated upper half of the body, vividly recalls the pictures, so common a few years ago, of the poor famine victims of India. The pelvis is a shapeless mass and it is impossible to locate any of the usual landmarks. Both thighbones, as such, are absent and the thighs are drawn up and curved in a way that would be ludicrous were it not so pathetic. Her height, which in health was sixty-four inches, is now but forty-two, measuring from the left heel, while from the right one it is several inches less. The legs below the knees seem now to be undergoing the morbid process. The accompanying photograph, kindly taken by Dr. Redeker, will show her appearance.

The arms are partially paralyzed, probably from pressure on the spinal nerves. The bowels and kidneys are performing their functions in a normal manner. She suffers severely at times, but the pain is rendered bearable by the acetanilid. By my advice they have never given her opiates.

PAPILLOMA OF THE LIMBUS CONJUNCTIVÆ.

GEORGE H. HEILMULLER, A.B., M.D.
Ophthalmic Surgeon to Washington Asylum for the Blind.
WASHINGTON, D. C.

I was consulted by an optician about the case here illustrated and as I could not see the patient until three days later a collyrium containing boric acid and suprarenalin was ordered. The suprarenalin constricted the blood vessels of the wart, producing the intense white appearance. The larger vessels were not contracted to the same extent and hence appear more prominently on the photograph.

The patient had no warts on other parts of the body. It first appeared in October, 1902, and was then the size of a pin head.

The photograph being life size, the tumor needs no description, it being a simple cauliflower-like wart. The tumor is on the patient's right side, the white irregular spots on the left being the image of the photographer's screens.

It is interesting on account of the extreme rarity of its appearance in the limbus. Usually tumors of this region are malignant. It is the first case of the kind that I have seen in a service of one and one-half years as clinical assistant at the Royal London Ophthalmic Hospital, one and one-half years' study in the clinics of Germany and France, and five years' private practice. Papillomas are seen now and then in the region of the caruncle, from which they seem to grow.

The growth was removed by excision, the conjunctiva was not stitched, the bare surface being covered in 48 hours by proliferation of conjunctival epithelium. Microscopic examination showed a typical wart structure, i. e., vascular papillæ covered by epithelium and no tendency to infiltration of underlying parts by epithelial cells.

These warts must be thoroughly removed as they are prone to recur and also because they cause some disturbance of vision.

THE RECENT ADVANCES IN OUR KNOWLEDGE OF AGGLUTINATION.

The agglutination or specific-serum test for typhoid fever has for some years held a deservedly high place as a practical aid to diagnosis, and it is now evident that the same test is becoming practically indispensable for the identification and differentiation of the numerous varieties of the typhoid bacillus, the dysentery bacillus, the members of the *B. enteritidis* group and allied forms. Every careful experimenter, however, has recognized the existence of manifold sources of error in the ordinary methods of application of this test, and will warmly welcome the recent advances in our knowledge which seem to lay bare the inner meaning of the phenomenon. It is, perhaps, more true of the agglutinins than it is of any other member of that remarkable group of bodies, brought to our knowledge by the researches of Ehrlich and his coadjutors, that immediate practical conclusions can be drawn from the somewhat abstrusely reasoned experiments.

Within the last twelve months the obscurity in which the real nature of the agglutinins has been shrouded has been illuminated by a series of remarkable investigations. It has been convincingly shown by Bail,[1] Joos,[2] Eisenberg and Volk,[3] and others that the agglutinins are bodies of complex constitution containing a combining (haptophore) and a functional (agglutinophore) group. When, for example, the serum of an animal that has been inoculated with a culture of the typhoid bacillus is heated to 65 C. or subjected to the action of weak acids, the functional group of the agglutinating substance is so altered that the heated or acidified serum is no longer able to produce clumping of the specific bacillus. The haptophore, or combining group of the agglutinins, however, in spite of this treatment, remains intact, as is shown by the observation that when the heated serum is added to a culture of the appropriate organism the bacilli, while not agglutinated, are so affected that they can no longer be clumped by the addition of unheated active serum. In other words, combination between the haptophore group of the heated agglutinins and the corresponding receptors in the bacilli has taken place, and when active serum is added to the bacilli, it finds the receptors already occupied, and is unable to manifest its agglutinating power. In a strictly homologous fashion, typhoid and cholera bacteria, when treated by heat or dilute acid, lose the power to be agglutinated, but remain still able to bind the agglutinin. The agglutinable moiety of the bacterial substance is destroyed by heat, but the combining portion persists. These researches of Eisenberg and Volk have been entirely confirmed by Wassermann.[4] We must, accordingly, assume the existence of two substances in agglutinable bacterial cells, namely, a stable, combining substance and a labile, functional substance, the integrity of the latter being essential to the production of visible agglutination. Corresponding to these two constituents of the agglutinable substance present in bacteria we must assume two similar groups in the agglutinating substance of the serum. Here again, one of these, the combining element, is stable while the functional is readily destroyed or altered by various agencies.

Wassermann[4] has sought to discover the relation that the agglutinins bear to the other substances present in immune sera, such as the precipitins and the amboceptors. The observation that the complete precipitation of an immune serum with a sterile bacterial filtrate destroys also the agglutinative power is taken to indicate that the agglutinin is one of the substances thrown down in the precipitate. That the agglutinin constitutes one of the elements of the precipitate produced by adding an excess of bacterial filtrate can, in the light of Wassermann's researches, hardly be doubted. On the other hand, this author concludes that the agglutinin and immune body (amboceptor), at least in the case of *Bacillus pyocyaneus,* are two completely independent substances. The agglutination test (Gruber-Widal reaction) and the immunity test (Pfeiffer's phenomenon) are, therefore, to be regarded as two separate and unconnected reactions, as, indeed, has been inferred on other grounds by a number of previous workers.

Wassermann's researches on the partial agglutinins led to the conclusion also already reached by some other observers, that biologically distinct varieties of bacteria may possess common receptors, so that differentiation on the basis of agglutinating properties is in many cases difficult, in some impossible. In differentiation tests investigators should adopt the rule that the extreme agglutinating value of the serum for the specific bacillus be used as a basis rather than any arbitrarily selected dilution standard. Thus a serum, the limit of whose agglutinating power is 1/20,000, can not be legitimately used for species differentiation in so low a dilution as a serum whose agglutinating power is only 1/500, since in similar dilutions the former would be much more liable to contain partial agglutinins for other species than the latter. It is further evident from the researches of Smith[5] and others that the reasons for the presence or absence of common receptors in biologically related species are by no means clearly understood.

Joos[6] has recently published investigations on the different agglutinins of typhoid serum, which demon-

strate with particular vividness how serious are some of the difficulties to the successful study of these substances, and how many pitfalls beset the steps of the unwary. This author has shown in a series of carefully planned experiments that living typhoid bacilli contain two different agglutinable substances which may be distinguished from one another by their different resistance to heat; one (the α-agglutinogen) is quickly destroyed at 60 to 62 degrees; the other (β-agglutinogen) can resist the action of this temperature for at least several hours. The inference from even this brief statement is obvious. Much work that has been done by previous students of the agglutinins is without sufficient regard to uniformity in the use of heated or unheated cultures, and it is evident that if Joos' statements are confirmed a fruitful source of error is here uncovered.

At least one important practical conclusion to be put to immediate use can be drawn from the results of all these researches, whatever value one may attach to the more or less theoretical interpretations by which they are accompanied. This is the need for extraordinary precaution in the whole technic of the agglutination test, whether the test be employed for diagnosing disease or for differentiating allied species of pathogenic microbes. It must be recognized that the agglutination phenomenon is a remarkably complicated process, and that apparently justified conclusions may be wholly vitiated by inattention to seemingly trivial details, such as the age, character and condition of the culture used for immunization, the ages of the serum as possibly influencing the formation of agglutinoids, the nature of the fluid chosen for diluting the serum, the degree of serum dilution, the age of the culture on which the serum is tested, alkalinity of the nutrient medium on which the culture is grown, the difference in the agglutinability of various bacterial stocks and many other factors. It is inevitable, if, from the purely human standpoint, perhaps somewhat unfortunate, that the whole tendency of advancing science should be to show that the apparently simple is in reality endlessly complex.

THE POINT OF ATTACK IN PULMONARY TUBERCULOSIS.

If one critically considers the number of points in medical science that are positively established he may be surprised at finding how very few they really are. There are not many topics, however hackneyed they may seem, that do not offer plenty of opportunity for fruitful investigation, for there are always new methods that can be tried, and new positions from which to view the facts. This absence of finished study does not, however, reflect on medical science, as might seem at the first thought. Every other branch of science is in the same condition, more or less according to its age and nature. It is told of a scientist who once made the remark in the presence of a number of his fellows that there was no subject that was not still open for fruitful research. The statement was questioned, with the result that the speaker agreed to undertake research in any topic that might be selected by his challengers. After some consideration "water" was chosen as being a substance that had been pretty thoroughly investigated. A long period of labor was followed by a monumental publication on this subject, in which were produced many new and important observations that added greatly to chemical and physical knowledge.

It might seem that the subject of pulmonary tuberculosis should by this time have been worked out to completion, in view of our familiarity with the disease and its cause, the enormous material it offers for study, together with the ease of its experimental production. However, the manner of production of the initial lesion, among other things, is still a matter of discussion, dispute, and study. For a long time we have been content with believing that the process started in some bronchiole or air sac, into which a bacillus had been inhaled, and where it happened to find proper conditions for multiplication instead of meeting the more common fate of being swept out by the cilia, or devoured by a phagocyte. However, there were always those who contended that the bacillus reached the lung by some other route than the bronchi; that is, by either blood or lymph, but they were in the minority. So recently as 1899 the question seemed settled by the elaborate research of Birch-Hirschfeld. In an enormous autopsy material he found a small number of cases, thirty-two in all, that offered proper conditions for the study, namely, a single active focus of the disease. Twenty-eight of these foci were located in the mucosa of a middle-sized bronchus, most often the one going to the posterior part of the apex, where, of its entire extent, the lung has the least respiratory movement. There were but three of the series that showed what appeared to be a primary interstitial lesion that might suggest origin in the blood or lymph vessels. The conclusions drawn from this study were that the prevailing idea was correct; that the bacilli that caused the disease had been drawn into the bronchioles, where, in the part of the lung least capable of removing them by coughing, they lodged, multiplied, and produced a tuberculous lesion. With an abundant material and acknowledged ability, this research of Birch-Hirschfeld seemed conclusive. Not so to all, however. Aufrecht,[1] soon after, published his reasons for believing that pulmonary tubercles usually arise from vascular lodgment of the bacilli, and he has urged this view consistently since.[2] The bacteria enter the blood, he believes, through the tonsils, or cervical, mediastinal or mesenteric glands, particularly the tonsils. They lodge in small branches of the pulmonary artery, where they produce an infarcted area, which soon becomes cheesy, constituting a tubercle. A miliary tubercle, according to Aufrecht, is a thrombosed vessel with thickened walls. In support of Aufrecht's views, we may call attention to the fact that numerous recent studies have indicated that tubercle bacilli do quite readily enter

1. Berliner klin. Wochenschr., June 25 and July 2, 1900.
2. See article in the Journal of Tuberculosis, April, 1903.

the blood stream without evident local lesion, notably through the intestinal mucosa into the thoracic duct. However, to most physicians the bronchogenic invasion will still seem the more probable.

And now comes a Russian, Abrikossoff,[3] who, pursuing the method of Birch-Hirschfeld of collecting suitable primary lesions, studied them in serial sections, with the aid of the elastic tissue stain. This stain rendered it possible to recognize structural landmarks too far altered to be recognized by other methods, and disclosed the fact that the center of the tubercle was really in a bronchiole, although the involvement of the vessels described by Aufrecht was readily seen. He believes that the process begins in the bronchial wall, and that the involvement of the vessels is secondary, although he was able to demonstrate that it is possible to produce foci of tuberculosis in the lung by injecting bacilli into the ear veins of rabbits; and these foci were in structure quite similar to the foci of bronchopneumonia observed in his human cases. His work, then, on the whole, agrees with the idea that primary bronchial location of the lesion is the rule, although indicating that it is possible to have quite similar lesions produced by bacilli reaching the lungs through the blood stream.

In this connection Grober's[4] experiments are of interest. He found that if suspensions of india ink were injected into the trachea of dogs, within six hours the particles could be found free in the pleural cavity. This, of course, indicates the possibility that primary tuberculosis of the pleura can be produced in a similar way by inhaled bacilli. If the ink were injected into the tonsils the pigment entered the cervical glands, and from there passed to the pleura, particularly that over the apex, but also some reached the pericardium and diaphragm. Thus another suspected route of invasion is proven to be possible.

NEW INVESTIGATIONS CONCERNING THE FIXATION OF TETANUS TOXIN BY CEREBRAL TISSUE.

When cerebral tissue is mixed with tetanus toxin, there occurs some form of union between the two which has been spoken of as a neutralization of tetanotoxin, due to its combining with the lateral chains or receptors of the nerve cells. This phenomenon was studied especially by Wassermann and Takaki, and by them and others marshalled into line as one of the strongest supports of Ehrlich's side-chain theory of cytolysis and immunity. Some recent experiments by Besredka and others are of interest in connection with the study of toxins. Besredka[1] finds that washed tetanized cerebral tissue (large quantity of tetanus toxin is added to the cerebral tissue of guinea-pigs, and after from six hours to three days the tissue is washed until the wash-water is wholly harmless when injected) produces fatal tetanus in mice in doses of one or two drops. This experiment certainly shows that more tetanotoxin is fixed by the cerebral substance than is neutralized. Besredka further shows that tetanus antitoxin has the power to abstract from tetanized cerebral tissue all the toxin it has fixed, thus leaving the tissue free to attach to itself again just as much toxin as before.

Dmitrievsky[2] endeavored to determine the relative amounts of antitetanotoxin in brain tissue and blood of immunized animals. He reasoned that if the overproduction of receptors in the nerve cells constitutes the source of the antitoxin, then the brain of immunized animals, at least at certain periods of immunization, would be richer in antitoxin than normal brains and than the blood of immunized animals' brains. He found that the blood of animals thoroughly immunized always contains more antitoxin than brain tissue, while this tissue in animals only partially immunized does not differ in its antitetanic power from normal brain substance. Whatever increase in antitetanic power—and it was always found to be only slight—there is in the brains of thoroughly immunized animals, Dmitrievsky ascribes to an increased amount of antitoxic blood retained in the hyperemic cerebral capillaries. The conclusion that the French investigators urge especially is that cerebral substance contains some principle that fixes tetanus toxin, but this principle is not the same as the antitetanin of antitoxic serum, and, consequently, the phenomenon of fixation of tetanotoxin by brain tissue can not be urged in support of Ehrlich's theory. It is not intended to do much more than merely to give the trend of these interesting studies. It may be pointed out, however, that, while cerebral tissue in the test-tube of Besredka's experiments failed to neutralize the tetanotoxin, it must be very doubtful, indeed, whether one is allowed to assume that brain tissue acts exactly in the same way when in the living body. At all events, the somewhat disturbing conclusions of the keen French investigators will be sure to stimulate the defenders of Ehrlich's theory to renewed inquiry.

A RADIUM CALCULATION.

A correspondent of the English periodical, *Nature,* has been calculating the amount of radium that would be required in the sun's composition to maintain its outgo of energy in the form of light and heat. Taking the most reliable figures as to the radiation of radium and of the sun, he finds that three and six-tenths grams in each cubic meter of the sun's bulk would be all that is required, excluding the possible, and, indeed, probable, conditions of the solar surface that would make even a smaller amount effective. These figures are rather startling, and aside from their general upsetting of accepted theories of the sources of solar energy, are formidable from another point of view. It is, perhaps, a fortunate thing that this new element, or whatever it is, is so scarce and hard to get. An ounce, or even a gram of radium might be an awkward thing to handle, and the isolation of a larger quantity be a positive danger to the community. In quantity, it might realize

the destructive powers of the "heat ray" used by the Martians in H. G. Wells' fiction, "The War of the Worlds." At present, the material has been studied just enough to excite the imagination, and its capabilities in that way seem limitless.

CHLOROFORM AND ITS DANGER.

The report of the special chloroform committee of the British Medical Association, published as a supplement to the *British Medical Journal* of July 18, especially that portion by Drs. Sherrington and Sowton, has a particular interest in view of the fact that, in spite of its known dangers, chloroform still holds its own as a popular anesthetic in surgery. The conclusions are, practically, that chloroform is a paralysant to the heart muscle; that it is rapidly taken up by the tissue, and that its paralyzing action is dependent in degree on the solution's percentage in the heart. They figure that 300 cubic centimeters of a 2 per cent. admixture of air and chloroform vapor in the arteries of a heart of an adult man would practically annul cardiac action. The practical application of this fact, however, requires further data as to the quantity reaching the cardiac arteries, the tension of the vapor in the mixture inhaled, etc. While a percentage of 2 per cent., or lower, of chloroform in the vapor inhaled is estimated to be within the limits of safety with moderate quantities inhaled, and a certain immunity is produced in the prolonged administration, the danger elements are not all eliminated. There still remains the possibility of idiosyncrasy which Sherrington and Sowton think existed in their experiments on cats, and which may in the more complex human organism be a still more serious probability. It is the unexpected that happens in accidents from anesthesia, and in chloroform we know that we have a direct cardiac poison, the absolute manageability of which under all conditions is by no means thoroughly established by this investigation. We can not fully indorse the view of the *British Medical Journal* that with inhalers supplying definite percentages, the probability of perfect safety in the use of this powerful agent is assured in the near future.

RESEARCH AND TEACHING IN CONNECTION WITH STATE INSTITUTIONS.

It is significant of the trend of the time to note that in several states active agitation in favor of the establishment of state pathologic institutes is going on. In New York the step has been definitely taken, and the Pathologic Institute of the New York state hospitals, as now reorganized and directed, promises to fulfill the expectations of its founders. Michigan has quietly advanced to the stage in which a separate building for the institute has been provided, equipment and salary assured, and it now remains to secure a director of this, a clinical and pathologic laboratory connected with the state university and a part of the state hospital's system of Michigan. The subject of a central laboratory has been brought to the notice of the board of control of the Iowa state hospitals. In Ohio the project was revived at the last meeting of the Ohio State Medical Association. Resolutions were adopted favoring the plan proposed by Ohlmacher in his paper[1] before the general session, and a committee appointed to advance the movement. The Ohio plan of having the initiative taken by the State Medical Association seems especially good, since this should tend to keep the control of the central laboratory in the hands of the medical profession of the state. As it is now organized, the medical profession of Ohio is in a position to secure favorable attention from the officials representing the people of the state, and with active work on the part of the committee the prospects for favorable results are bright. The day has passed when the various medical institutions of the states shall have fulfilled their duty to society by attending to administrative details alone. The medical profession and the intelligent public demand that these great hospitals with their thousands of patients and millions for maintenance shall be more than immense public hotels. Their vast material should be turned to the use of science. A small portion of the money set apart for their maintenance should be used toward investigating the nature, cause, treatment and prevention of the diseases for the care of which they are established. In the East, especially in Massachusetts and New York, a scientific spirit animates the medical staff of the state hospitals, several well-conducted laboratories are in flourishing condition, and contributions of scientific value have been produced. The movement is coming westward, as indicated by the facts above outlined, and it only remains for our state medical associations to vigorously bend their energies toward the realization of a scheme vastly important in its scientific and humanitarian promises.

Medical News.

ILLINOIS.

Swindlers Arrested.—Chester Parker and W. Fletcher Hall, so-called "magnetic physicians," who swindled many people of Peoria out of sums varying from $25 to $100 and decamped to Omaha, have been arrested there and will be brought back to Peoria for trial.

Quarantine To Be Raised.—Carterville, Marion and Murphysboro, which have been maintaining a quarantine against Herron, Williamson County, where there have been several cases of smallpox and ten deaths, have been requested to remove the embargo, as the situation has so improved as to render quarantine unnecessary.

Reforms at Dunning.—Superintendent Podstata of the Cook County Institutions at Dunning, announces that he will open a training school for nurses this winter. He has had on trial an attendant charged with having used violence to a patient, has found him guilty and discharged him, and has in hand an investigation of a charge of cruelty against a female attendant.

State Society Incorporated.—Incorporation papers of the Illinois State Medical Society were filed at Springfield, July 23. The object of the society is to promote the science and art of medicine. The incorporators are Dr. David W. Graham, Chicago; Otho B. Will, Peoria; William O. Ensign, Rutland; Henry C. Mitchell, Carbondale; L. J. Harvey, Griggsville; J. F. Percy, Galesburg; Carl E. Black, Jacksonville, and Edgar P. Cook, Mendota.

Chicago.

Held up and Robbed.—Dr. Charles M. Oughton was recently held up in front of his residence and robbed of a pocketbook containing $60.

Personal.—Dr. and Mrs. G. E. Fosberg sailed on the *Oceanic* for Liverpool, July 29.

1. The laboratory movement in Ohio's state hospitals.

Absurd Charge.—A constable who had left an umbrella in the office of Dr. T. Bassett Keyes, arraigned Dr. Keyes before a justice of the peace on the charge of larceny. Although the defendant's attorney made the plea that umbrellas were common property, the physician was acquitted.

Low Mortality.—Notwithstanding—or because of—the unusual character of the weather during the month just ended, says the Chicago Department of Health, the July death rate, 14.92 per 1,000 per annum, is more than 16 per cent. lower than the average of the ten previous Julys, which was 17.84. The highest July rate of the decade 1893-1902 was 24.43 in 1894; the average rate of the first five years was 21.15, and of the second, 15.12. This shows a decrease of nearly 30 per cent. in the two periods, and is evidence of the increasing healthfulness of Chicago. Had the death rate of the first half of the last decade still obtained there would have been 3,092 deaths last month instead of the 2,390 which actually occurred.

MARYLAND.

Baltimore.

Deaths.—There were 220 deaths for the week ended July 25, a rate of 20.97 per 1,000 per annum, that for whites being 17.06 and for colored persons 42.49; 100 were of children under 5; 42 new cases of typhoid fever were reported.

Summerers.—Dr. William Osler is summering at St. Martin's, Guernsey, England.——Dr. William E. Moseley sailed for Liverpool, July 24.——Dr. Harry Friedenwald sailed for Bremen, July 21.——Dr. J. Williams Lord will spend the next two months near Salem, Mass.——Dr. G. Frank Jones is at White Sulphur Springs, Va.——Dr. J. W. Smith is making a tour of Colorado.——Dr. Andrew H. Whitridge is in London. ——Dr. James A. Bond of Westminster, Md., is in Paris.——Dr. John G. Jay sailed for Europe, August 1.——Dr. John N. Mackenzie is spending August at Narragansett Pier.——Dr. B. Merrill Hopkinson is at Prout's Neck, Maine.

The Bahama Expedition Returns.—The expedition of investigation sent to the Bahama Islands, June 1, by the Baltimore Geographical Society and Johns Hopkins University, returned July 30. Many valuable data were obtained. Dr. Penrose, in charge of the medical department, examined 1,100 sick persons. Owing to the poor living and small fees of physicians, the natives have but little medical treatment. Leprosy and other skin diseases were very prevalent, and were closely studied. On several occasions the pilots and provision vendors were found to have leprosy. The degenerates of Abaco, descendants of the Torys, who intermarried closely, were studied. No yellow fever was found, and only two cases of malaria. Many species of mosquito were found and brought back to be studied by Dr. Howard, government entomologist.

NEW YORK.

Personal.—Drs. Charles Cary and A. L. Benedict, Buffalo, have returned from Europe.

Hospital Enlarged.—The trustees of the Buffalo General Hospital have added eighteen private rooms and nine semi-private rooms to the hospital.

Crippled Children Have Outing.—The little patients of the New York State Hospital for Crippled Children were the guests of the "Robins' Nest" at Tarrytown, a branch of the New York Hospital for Ruptured and Crippled, and had a very enjoyable outing.

Saratoga Spring Water.—The United States Government has sent Prof. F. B. Weeks of the Geological Survey to Saratoga to examine and prepare a report on the mineral springs of that section of the state. This report, containing scientific and reliable data, is to form a part of the novel mineral springs exhibit to be included in the World's Fair at St. Louis.

New York City.

Personal.—Dr. R. Husted Bell has assumed editorial charge of the *Medical Mirror*, as successor to the late Dr. I. N. Love. ——Dr. Henry L. Shively has been appointed a visiting physician to St. Joseph's Hospital.

False Death Certificate.—Dr. Frank A Bigelow, the physician in charge of the New York branch of the Koch Lung Cure, was held by Magistrate Hogan for trial in the Court of Special Sessions on the charge of making a false death certificate.

City Hospital for Consumptives.—The commissioner of charities has applied to the Board of Estimate for an appropriation sufficient to permit the erection of a new out-of-town hospital for consumptives. It is recommended that accommodations be provided for 500 patients, and that cheap wooden buildings be erected for dormitory purposes. It is urged, however, that the hospital grounds should cover 250 to 400 acres. It is estimated that the land will cost from $100 to $250 per acre, and that the annual cost of maintenance will be about $182,500.

Suit Against Hospital.—The death from burns of a patient who was being prepared for operation in the General Memorial Hospital has already been noted in these columns. The woman's husband has now begun an action in the Supreme Court against the hospital to recover $100,000 damages, alleging that the death of his wife was due to the carelessness and inexperience of the nurse who, instead of making use of the electric light, placed a lighted candle in a tumbler on the bed, and thus caused the ignition of the alcohol and ether which she was using. It is said that this suit involves certain novel points.

Office Thief and Crank.—Brooklyn and the upper west side of Manhattan have been "worked" by a young man of 22, calling himself variously Frank Edwardson, Edwards and Henderson, and giving an address as 2008 or 2274 Eighth Avenue. He is five feet six inches in height, weighs 130 pounds, has a clean shaven face, hollow cheeks and bad teeth, and dresses in a dark gray suit and dark gray felt hat. He gives his occupation variously as electrician and piano tuner, and complains of sudden attacks of choking due to spasm of the esophagus. He comes in with such an attack, but on engaging him in conversation it is noticed that his difficulty gradually subsides, and he impresses one as a nervous crank. His visits in a number of instances have been immediately followed by robberies.

PENNSYLVANIA.

Typhoid Epidemic.—An epidemic of typhoid fever is reported at Lancaster; the infection has been traced to the pollution of a well by a cesspool.

Investigation of Milk.—Two deaths at Johnstown, traceable to the use of drugs to preserve milk, are said to have prompted State Dairy and Food Commissioner Warren to undertake an investigation of the milk in the market. One thousand samples were obtained throughout the state. Of these, 75 per cent. contained formaldehyd or other preservative fluid. Many suits against dealers are likely to be instituted. A crusade has also been begun against the manufacture and sale of deleterious flavoring and coloring extracts used in beverages. Some of the manufacturers have been arrested and held in bail. The attorney-general has notified Commissioner Warren that he has ample grounds for prosecuting managers of almshouses and penal and charitable institutions of the state who furnish oleomargarine to the people under their charge.

Philadelphia.

New Hospital.—A new hospital, to be known as the Union Mission Hospital, is to be built by the John B. Stetson Company, on Fourth Street, below Montgomery Avenue. The hospital is to be a three-story fireproof brick structure, 65 by 102 feet. A roof garden will surmount the building.

After Toy Pistol Dealers.—Acting on the advice of District Attorney Bell, in a communication sent by him to Director of Public Safety Smyth, the latter has detailed detectives to investigate the sale of toy pistols from which resulted the recent deaths from tetanus. The district attorney will co-operate in the investigation.

Disclaimer.—In regard to criticism of the conduct of the Municipal Hospital, Director Martin positively disclaims any intention to criticise Dr. William M. Welch, for twenty-five years physician in charge. Dr. Martin is quoted as saying: "The feeling of the department is that the best and most efficient administration of the Municipal Hospital could be accomplished by a resident physician, but there is no intention of dispensing with Dr. Welch's services, since in the medical work of the city, in both ability and experience, he is invaluable." Dr. Welch's management of the institution was recently strongly endorsed in resolutions passed by the Medico-legal Society.

Polyglot Talks to Mothers.—The department of health has arranged to give a series of plain talks to mothers on the care of babies. Representatives of church guilds, day nurseries, college settlements and other charitable organizations arrange for the time and place of meeting. The following physicians have volunteered to give these lectures: H. C. Carpenter, W. S. Cornell, Frederick Fraley, Jr., Henry Golden, W. G. B.

Harland, Wilmer Krusen, W. W. Naylor, Francis Patterson, Robert N. Willson, and S. Doskow, D.D.S. Some of the talks have already been given, and part of them are to be given in foreign languages.

RHODE ISLAND.

To Suppress Smallpox.—Woonsocket has appropriated $1,600 in addition to sums previously appropriated for the purpose of suppressing the smallpox epidemic in that city.

Smallpox at Valley Falls.—On July 17, nine cases of smallpox were reported to the health officer, some of the patients being operatives in mills at Valley Falls, Central Falls and Lonsdale.

Fiske Prize Awarded.—The Caleb Fiske Prize of $250 for the best essay on "Auto-intoxication as a Cause and Complication of Disease" was awarded to Dr. W. Lewis Chapman, Providence. The subject for the prize essay next year is "The Action of Light as a Therapeutic Agent."

Free Camp for Consumptives.—The free camp for consumptives, prepared at Foster, under the direction of Dr. William H. Peters, Providence, was ready to receive patients, July 9. Out of 28 applicants for the open-air treatment, 21 have been accepted as cases in which the disease can be arrested.

TEXAS.

In Hadra's Memory.—The Dallas County Medical Society held a special meeting July 13 to take suitable action on the death of Dr. Berthold E. Hadra.

Texas Sanitarium.—The Texas Sanitarium, recently incorporated, has purchased 40 acres of land and buildings near Leona, and will complete and equip the buildings as a sanitarium.

Personal.—Dr. J. Shelton Horsley, El Paso, has accepted the chair of principles of surgery at the Medical College of Virginia, Richmond. He has also been elected to one of the positions of attending surgeon to the Memorial Hospital. He expects to leave El Paso on July 6, and after a vacation will locate in Richmond by the middle of August. Dr. Horsley has turned over interests in St. Luke's Hospital to Dr. C. B. Hanson.——Dr. John O. McReynolds, Dallas, has had conferred on him the degree of LL.D. by the Kentucky University.

UTAH.

Smallpox.—In Salt Lake City, on July 19, there were 10 cases of smallpox, and at Huntsville, where there are more than 15 cases, the citizens claim that quarantine laws are absolutely ignored.

Physician Acquitted.—Dr. Edward S. Payne, Salt Lake City, on trial for murder in the second degree for the death of Miss Anna D. Hill, who it was alleged died in his office after a criminal operation, in December last, has been acquitted.

Site for Isolation Hospital.—An eighty-acre tract of land near Terrace Heights has been selected as the site for the new isolation hospital for Salt Lake City, and bids were asked for the construction of a building to accommodate 75 patients.

Personal.—Dr. Haymond J. Powers, Ogden, who recently took aconite, mistaking it for other medicine, and was very ill for a time, has recovered.——Dr. Andrew J. Hosmer, Salt Lake City, has been appointed surgeon of the Salt Lake division of the San Pedro, Los Angeles and Salt Lake Railroad.

WASHINGTON.

Hoquam Hospital.—Hoquam is to have a new hospital, to cost about $10,000, with 35 ward beds and 16 private rooms. The building is to be completed October 1.

New Hospital for Spokane.—Ground has been broken for the new St. Luke's Hospital, Spokane, to cost about $26,000, all but $8,000 of which has already been subscribed.

Personal.—Dr. Thomas B. Curran, Tacoma, has been appointed county physician, vice Dr. Fred C. Miller, deceased.——Dr. H. W. Allen has been appointed health officer of Spokane, succeeding Dr. De Witt C. Newman, resigned.

Physicians Fined.—The Supreme Court has sustained the lower court in the case of Drs. James G. Stewart and Oscar V. Lawson, Seattle, convicted of conspiracy to obtain possession of the examination questions used by the State Board of Medical Examiners at its session in January. A fine of $500 was imposed in each case, and this fine, the Supreme Court holds, must be paid.

State Board of Medical Examiners.—On July 9 the State Board of Medical Examiners elected Dr. Frantz H. Coe, Seattle, president; Dr. H. A. Wright, Wilbur, vice-president; Dr. Philip B. Swearingen, Tacoma, secretary, and Dr. J. M. P. Chalmers, Vancouver, treasurer.——Dr. Caspar W. Sharpless, Seattle, has been appointed a member of the board, vice Dr. William C. Cox, Everett, term expired.

WISCONSIN.

Damages Awarded.—In the suit of Peter Hay against Dr. John Baird, Superior, for alleged malpractice, the jury awarded the plaintiff damages of $4,624.50.

Insanity on the Increase.—The report of the State Board of Control for the fiscal year ended June 30 shows an increase of 197 cases of insanity in the state, or nearly four per cent.

State Board Changes.—The item regarding Dr. L. E. Spencer, Wausau, in THE JOURNAL of June 20, was incorrect in this particular, that he succeeded Dr. J. Henry McNeal, Fond du Lac, term expired, as member of the State Board of Health, and not Dr. George W. Harrison, Ashland, who is still a member of the board.

Medical Examiners.—At its meeting in Madison, July 16, the board elected Dr. John R. Currens, Two Rivers, president, and Dr. Filip A. Forsbeck, Milwaukee, secretary and treasurer. These officers, and Dr. John V. Stevens, Jefferson, were chosen to represent the board in regard to interstate reciprocity of license.——Drs. Adellon P. Andrus, Ashland, and Frank P. Klahr, Horicon, have been appointed members of the board, succeeding Drs. Harvey B. Dale, Oshkosh, and Charles E. Quigg, Tomah. Dr. Wilbur T. Sarles, Sparta, and Louis F. Bennett, Beloit, have also been appointed members of the board.

GENERAL.

Opium Investigation.—The Philippine commission has appointed a committee to co-operate in an investigation of the use of opium in Japan, China, Singapore and Burmah. Major and Surgeon E. C. Carter, commissioner of public health in the Philippines, Bishop Brent of the Episcopal Church, and Dr. Albert are the federal members of the committee.

CANADA.

Montreal May Build a Hospital For Consumptives.—The medical men of Montreal are presenting to the city council at its next regular meeting an important petition. This is backed by the provincial board of health, and will call on the city to vote a generous sum for the erection of a hospital in Montreal for the treatment of tuberculosis.

Annual Report of British Columbia Board of Health.—Dr. C. J. Fagan, secretary of the British Columbia Board of Health, has issued his annual report. He states that the scheme for the establishing of a sanitarium for tuberculosis has now so far developed as to be capable of being put into practical operation within a short space of time. A site has been selected near Kamloops.

Vaccination in Montreal.—Over three thousand children left the Montreal schools this year refusing to be vaccinated. Last year the number debarred totaled 4,917. Dr. Laberge states that there is a steady growth among the citizens in favor of vaccination. That vaccination is beneficial has been abundantly proven in Montreal by the fact that of the last three hundred cases in that city, but one had been properly vaccinated. It is proposed to so amend the vaccination law as to leave pupils no option in the matter.

Smallpox in Cape Breton.—The spread of smallpox in the town of Sydney Mines, C.B., continues unabated, despite the efforts of the health authorities to check it. There are at present thirty cases in the hospital, and some fifty cases under quarantine. The people are averse to carrying out the instructions of the health authorities, hence the failure in the attempts to check the spread of the disease. General vaccination has been ordered, and four or five medical officers are conducting these operations. The disease has been prevalent in the town since May, since which time there have been upward of 100 cases. The town is isolated from outside intercourse as far as possible.

A Handsome Bequest to McGill Medical Faculty.—By the will of the late Mr. James Cooper of Montreal, the medical faculty of McGill University receives $60,000. The benefaction takes the form of an endowment to establish and maintain a chair of internal medicine, on lines to be determined by the medical faculty themselves. The fund is to be known as the Cooper Endowment Fund, and is to be payable two years after the date of death. A sum of $25,000 payable at the same time as above, is also left to the hospital for crippled children now

being organized by Dr. A. McKenzie Forbes, to be known as the Children's Memorial Hospital to Our Late Queen Victoria. Drs. T. G. Roddick, M.P., and Charles F. Martin are two of the executors of the will, and the residue of the estate is to be disposed of as the executors see fit within the next twenty years among the following institutions: The Montreal General Hospital, the Brewery Mission, the Salvation Army, and the Y. M. C. A.

FOREIGN.

The Journal of the Royal Army Medical Corps.—The first number of this journal, the official organ of the British military medical service, has just appeared. The first number contains interesting papers on hospital arrangements on transports, reports of surgical cases, and an account of the medical relief expedition to Martinique and St. Vincent last year. These, with other matters of interest especially selected for the class of readers whose patronage is expected, make a very creditable number. The journal is being issued monthly under the editorial management of Major R. H. Firth. Its appearance and general make up is excellent.

Hospital Training Required of German Students.—The medical students of the University of Berlin protest against the new regulation which requires that all who have not finished their course and taken their state examination before Oct. 1, 1903, will have to pass through the practical hospital year. This regulation affects those students who, during their studies, have exhausted their financial resources. There are many who have acted as assistants in the different departments, but this will not be credited to them as an equivalent. The students of Halle and Heidelberg have also protested to the chancellor of the empire against the new regulation.

The plague in Sydney reappeared June 20, only one case being reported, and no more occurring up to June 29. It is interesting to note that 115 rats infected with the plague had been found among those examined since March 12. A bounty of a sixpence a rat is now paid at Sydney. The destruction of rats has been continued ever since the epidemic that ended June 12, 1902, but with poor success in certain quarters of the city, where private parties failed to avail themselves of the means of extermination. Other cases of plague occurred May 24 and 25 in Brisbane and Perth, one each. A suspected case was isolated, June 25, in Auckland, N. Z.

Quacks in Germany.—Inquiry recently instituted as to the increase of quacks in German towns, brought out some interesting facts, though the replies to the inquiries were not as general and complete as was desired. In the province of Breslau, there were reported 228 quacks and 98 cases of malpractice, with 17 deaths at their hands; of these, 44 occurred in the town of Breslau, with two deaths. Of the 228 quacks, 141—113 men and 28 women—throve in the town of Breslau, and 70 who were not resident there treated Breslau patients, and visited occasionally. In the Rhine province, the inquiry brought out the result that from the 2,351 resident physicians in 539 communities, there were received 86 reports from 71 localities, which gave account of 288 quacks in 198 towns. Of these 288 quacks, 132 were reported from the province of Dusseldorf.

Smallpox in Tasmania appeared at Launceston in June, and a dozen or more cases occurred in that month. Rigid quarantine was established, the running schedules of steamships were modified and business interfered with. Houses and streets were put under guard, the general hospital closed, all outgoing mail fumigated and vaccination was general. New South Wales declared Tasmania an infected island, and took measures to keep smallpox out. The *Sydney Herald* remarks that there is perhaps no disease of which their people stand more in dread than smallpox. Australia has been free from it for many years. Partly because of supposed security by water isolation and partly because of trust in sanitary officers at the ports of entrance, vaccination has not been very general, and smallpox, it is thought, would deal severely with the people if an epidemic were once started.

Successful Mosquito Campaign at Suez.—According to a letter received by Major Ronald Ross from the secretary-general of the Canal Company of Suez at Paris, it appears that the measures taken by the local health authorities at Ismailia have almost completely eradicated the mosquito pest in that place. A permanent department has been created for oiling cisterns and pits, suppressing marshes and pools of water, and he thinks the number of cases of fever is very sensibly diminished in comparison with corresponding periods of former years. While the anopheles has not been completely exterminated, the recently-captured insects do not appear to be contaminated, while the culex mosquitoes, including, as Dr. Ross seems to think, the stegomyia, have almost disappeared. There is every reason to hope that the efforts will end in the complete extinction of malaria in the town of Ismailia.

Sanitary Problems in the Transvaal.—It is said that the South African medical authorities, especially in the Transvaal, are decidedly sluggish in sanitary matters, and the prospects of new outbreaks of plague are not just what might be desired. The local authorities seem to fail to appreciate the needs of sanitation, and in one case that is mentioned in the correspondence of the *British Medical Journal* they are directly interested in slum property and correspondingly opposed to measures that would tend to its sanitary amendment. The character of the obstinate persistency of the plague in Port Elizabeth has been alleged by the colonial secretary to be directly due to the opposition of the local authorities to the recommendations of the colonial health office.——A new rat-infested center has lately been discovered in Cape Colony, and it is possible that there may be a serious epidemic to follow. From the character of the population in the district the outlook in case such occurs is not hopeful.

Correspondence.

Reciprocity.

BURLINGTON, IOWA, Aug. 1, 1903.

To the Editor:—About a year ago you did me the honor of publishing my views about "the one simple and practical way of getting reciprocity in the practice of medicine," namely: amendment to that effect in the medical laws of all the states. I see in the current issue of THE JOURNAL that Vermont and Oregon have just such amendments, and while I am not vain enough to suppose that my views above referred to were in any way responsible for such action, I am none the less pleased to see that other people are as little visionary about this matter as I am.

H. B. YOUNG.

Surgical Treatment of Nephritis.

SAN FRANCISCO, July 24, 1903.

To the Editor:—I notice in THE JOURNAL, July 4, an article by Dr. A. H. Ferguson on the above subject, in which he refers to my experimental work on decapsulation of the kidney (*Annals of Surgery*, April, 1903). I wish to call attention to two points in which he is in error in his criticism of my paper. He says:

> It must be observed that in these experiments the kidneys of the dogs were normal and did not require additional blood channels for physiologic purposes, and also the organs were returned within the fatty capsule, which is but sparsely supplied with blood vessels.

It is true that the kidneys were normal, but it is also true that in two experiments, Nos. 4 and 6, an additional supply of blood was demanded; in the first instance by the renal artery of one kidney after decapsulation of the other; in the second instance by removing one kidney and leaving the other undisturbed. In meeting the demand for increase of function made on both the normal kidney and the decapsulated kidney, the perirenal circulation played no part. It was fulfilled by the enlargement of the renal artery and vein in both instances. In the latter part of the sentence, quoted from the article of Dr. Ferguson, he objects to my not having removed the fatty capsule, "which is but sparsely supplied with blood vessels." In reply to this objection to the validity of these experiments I would state that, in the dog, the peritoneum is closely adherent to the greater part of the surface of the true capsule, that there is no fatty capsule, and that, therefore, it can not be removed.

HAROLD A. JOHNSON.

Vaselin as a Menstruum.

OAKLAND, CAL., July 29, 1903.

To the Editor:—In the discussion on the paper "Treatment of Scarlet Fever, Its Complications and Sequelæ," by Dr. H. M. McClanahan, July 4, Dr. G. A. Hermann refers to the method of

preparing a 10 per cent. ointment of carbolic acid in vaselin, while the Doctor does not state that he uses this strength in the ointment. One would infer that he does, or why does he mention it at all?

I wish to emphasize the absolute pharmaceutic incompatibility of a 10 per cent. ointment of vaselin, a 5 per cent. or even a 3 per cent. ointment of this hydrocarbon, which is altogether devoid of oxygen; 2 per cent. carbolic acid is all it will take up; 3 per cent. can be made by mixing equal parts of carbolic acid and camphor and then adding the vaselin. Even a 2 per cent. must be most thoroughly macerated, and any fraction over this amount will cause the crystals to precipitate.

The tendency of carbolic acid crystals in any menstruum is always to coalesce, and this is the cause of the frequent carbolic acid burns we so often witness—not the 2 per cent., but the precipitated crystals in excess of this amount.

Highly oxidized oils, as lard or lanolin, will take up 25 per-cent. of carbolic acid or more; so will olive oil or cotton seed oil take up a considerable amount, but never petrolatum. The oxidized oils or fats are readily absorbed into the system. The non-oxidized or hydrocarbons never. Therefore govern your strength accordingly. I do not write this as a correction, but want to emphasize what the Doctor suggests and give a reason for it. Carbolated vaselin is a good external application in scarlatina, as it will, in a sense, prevent the absorption of the acid, but lard, lanolin and vaselin should never be considered under the same heading as a base for active poisons.

Again, the profession almost universally prescribe vaselin a proprietary article, the exclusive monopoly of one firm. If we would be more just to American manufacturing chemists, if we would be more technical in our scientific language, and more considerate of the price of prescriptions to our patients we would call it petrolatum.

M. Lewis Emerson, M.D.

Marriages.

W. T. McCarty, M.D., Bison, Okla., to Miss B. L. Folsom of Chicago.

Lawrence Newton Wheeler, M.D., Monrovia, Cal., to Miss Helen Grace French of Berkeley, Cal.

William B. Mantle, M.D., Albion, Iowa, to Miss Hattie Leah Sawyer of Mount Vernon, Iowa, July 15.

Arthur Tenney Holbrook, M.D., Milwaukee, Wis., to Miss Bertha Matson Andrews of Lombard, Ill., July 29.

G. E. Leavitt, M.D., Mason Valley, Nev., to Miss Mary Cecilia Johns of Georgetown, Cal., at Smith, Nev., July 1.

Deaths.

Louis D. Kastenbine, M.D. Bellevue Hospital Medical College, New York, whose reputation as a chemist was widespread, died from Bright's disease at his home in Louisville, Ky., July 29. He was born in Louisville, Jan. 1, 1839, and was educated in the public schools, graduating in 1858. While attending the high school he took a course in chemistry in the medical department of the University of Louisville, under Dr. James Lawrence Smith. He began the study of medicine at the University of Louisville in 1860, with Dr. Erasmus D. Force and A. B. Cook as his preceptors. When the Civil War broke out he attached himself to the Federal Army as an acting medical cadet, being assigned to the duty in Louisville at Military Hospital No. 4. After his graduation Dr. Kastenbine remained in New York some time, returning to Louisville and associated himself with Dr. E. D. Force. He was selected as the first demonstrator of anatomy of the Kentucky School of Medicine in 1865. Later he was made associate professor of chemistry in the University of Louisville. In 1878 he took the chair of chemistry and toxicology in the Louisville Medical College. A few years ago he resigned and accepted the chair of chemistry in the Louisville College of Pharmacy, in connection with which he became renowned as an analytical chemist. He was special examiner of drugs of the port of Louisville for the United States government.

Thomas Moore Rochester, M.D. University of Buffalo, 1878, of Brooklyn, for three years president of the staff of and later consulting surgeon and gynecologist for the Brooklyn Central Dispensary, attending surgeon to St. John's Hospital, special lecturer in physiology at the Long Island College Hospital, vice-president and for two years president of the King's County Medical Association, charter member of the New York State Medical Association, died from consumption, July 12, at the home of his mother in Rochester, N. Y., after an illness of three years, aged 48.

Edwin J. Miller, M.D. Jefferson Medical College, Philadelphia, 1896, of Intercourse, Pa., was thrown from his carriage in a runaway accident near Mount Airy, July 24, and sustained a fracture of the skull, from which he died two hours later, aged 35. He was a member of the Lancaster City and County Medical Society, the Pennsylvania State Medical Association and the American Medical Association.

John Phillips, M.D. Rush Medical College, Chicago, 1853, a member of the American Medical Association; for more than 50 years a resident of Stevens Point, Wis., who served both in the senate and assembly of his state, died at his home in Stevens Point, July 28, from heart disease following influenza, after an illness of several months, aged 79.

George W. Nash, M.D. Central College of Physicians and Surgeons, Indianapolis, 1888, a coroner of Marion County, Ind., from 1898 to 1900, died at his home in Indianapolis, July 26, from paralysis, aged 68.

Lawrence Stewart Edwards, M.D. Bellevue Hospital Medical College, New York, 1876, who served for two terms as coroner of Suffolk County, N. Y., died suddenly at his home in Patchogue, Long Island, July 25, from apoplexy, aged 48.

Clarence B. Le Van, M.D. Niagara University, Buffalo, 1888, died, July 26, at his residence in Buffalo, aged 39. He was a member of the Buffalo Academy of Medicine, Erie County Medical Society, and the Esculapian Club.

A. E. Rodgers, M.D. Medical College of Ohio, Cincinnati, steward at the Bonner Springs (Kan.) Sanitarium, was burned to death, July 16, while endeavoring to save the life of an aged and infirm patient, aged 33.

Charles A. Ring, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1872, professor of obstetrics in the Medical School of Maine, died at his home in Portland, July 8, after a long illness, aged 58.

Thomas C. Walton, M.D. University of Pennsylvania, Philadelphia, 1878, died at his home in Stroudsburg, Pa., July 10, from dropsy, after an illness of fifteen weeks, aged 49.

James Morgan Woodall, M.D. Vanderbilt University, Nashville, Tenn., 1889, died at his home in Estill Springs, Tenn., July 18, after an illness of two days, aged 36.

John Evans Walker, M.D. New York University, 1886, died at his home in Columbus, Ga., July 23, from cerebral hemorrhage, after an illness of only a few hours.

Edmund Brink, M.D. Berkshire Medical College, Pittsfield, Mass., 1856, died at his home in Saugerties, N. Y., July 21, after a prolonged period of ill health.

Arthur E. Graham, M.D. Vanderbilt University, Nashville, Tenn., 1885, died at his home in Handley, Texas, July 23, after a long-continued illness, aged 46.

Horace B. Van Norman, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1864, died at his home in Cleveland, July 9, after a short illness, aged 69.

James W. Blount, M.D. University of Pennsylvania, Philadelphia, 1845, died at his home in Kenansville, N. C., July 15, from heart disease, aged 80.

John M. Wilson, M.D. Medical College of Ohio, Cincinnati, 1851, died at his home in Williamstown, Ky., July 20, after a lingering illness, aged 71.

Abraham O. Scott, M.D. University of Pennsylvania, Philadelphia, 1853, died at his home in Fairfield, Pa., July 7, from senile debility, aged 78.

Pierre Forstall Choppin, M.D. Tulane University, New Orleans, 1884, of St. Patrick's, La., died at Covington, La., from la grippe, July 15.

I. C. Wait, M.D. Rush Medical College, Chicago, 1858, died suddenly from heart disease at his home in Juliaetta, Idaho, July 15, aged 70.

Charles A. Morin, M.D. Laval University, Quebec, 1890, died suddenly at his home in Thedford Mines, Que., July 24, aged 37.

Rachel H. Allyn, M.D. New England Female Medical College, Boston, formerly of Lowell, Mass., died at East Charleston, Vt., July 22, aged 93.

Boswell Ward, M.D. Rush Medical College, Chicago, 1860, of Indianapolis, died at Winona Lake, July 9, after a prolonged illness, aged 73.

Sardis B. Taylor, M.D. Starling Medical College, Columbus, Ohio, 1875, died suddenly at his home in Fremont, Ohio, July 15, aged 60.

Frederick William Payne, M.D. Harvard Medical School, Boston, 1866, died recently at his home near Boston, after a long illness.

Joseph J. Cox, M.D. Jefferson Medical College, Philadelphia, mayor of High Point, N. C., died at his home in that place July 19.

Walton H. Yager, M.D. University of Louisville, 1891, died at his home near Worthville, Ky., July 13, after a short illness.

A. V. Roberts, M.D. University of Pennsylvania, Philadelphia, 1848, died at his home in Mansfield, La., July 8, aged 78.

E. Barnes, M.D. University of Louisville, 1875, died at his home in Tulia, Texas, July 16, after a brief illness.

H. N. Sherrill, M.D., of Union City, Tenn., died at his home in that place from heart disease, July 18.

Book Notices.

THE AUTOBIOGRAPHY OF A THIEF. Recorded by Hutchins Hapgood. Cloth. Pp. 349. Price, $1.25 net. New York: Fox, Duffield & Co. 1903.

This work purports to be a true statement of a reformed criminal, evidently edited by a more accomplished literary man, probably a newspaper man. It is an entertaining work in its way, giving certain views of low life from the standpoint of the criminal, and it does not create a very exalted impression of the police arrangements or the politics of the City of New York and other places. In fact, it bears out to a very large extent the allegations in Josiah Flint's work on the subject of the grafter in politics. The author, or rather the individual whose autobiography is here given, claims to be reformed, and his editor seems to have faith in his reformation. It is evidently not based on a moral conviction of sin, but rather on a utilitarian realization of the unprofitableness of crime as a means of support. The individual evidently has had considerable experience since he has had three state prison sentences and wound up in an asylum for the criminal insane, to which last place he gives a decidedly bad name. This is a little ungrateful since it seems to have been the principal means of his reform in breaking off the opium habit, etc. It is highly probable that his mental condition was such as thoroughly justified detention in such an institution, and he brings away the impressions based on his disordered mentality at the time. On the whole the work is a contribution to the sociologic literature of the day which has a certain tendency toward this kind of realism. We do not see any very great moral lesson to be derived from it, yet it is not directly bad in its tendencies, like the biographies of the James brothers and of other noted criminals that have so large and injurious a circulation. It is well to know something about the defects of the social organization and about the parasites that live on it. The subject of the autobiography evidently has a keen sense of humor and has done considerable reading in his prison detentions with the facilities there afforded. He does not, however, give us a high idea of discipline in our penal institutions. The book is suggestive of many reforms, and it may serve a useful purpose in this way.

HANDBOOK OF CLIMATOLOGY. By Dr. Julius Hann, Professor of Cosmical Physics in the University of Vienna. Part I—General Climatology. Translated, with the Author's Permission, from the Second Revised and Enlarged German Edition, with Additional References and Notes, by Robert DeCourcy Ward, Assistant Professor of Climatology in Harvard University. Cloth. Pp. 437. Price, $3.00 net. New York: The Macmillan Company, 1903.

This work, which is the first or general volume of a still larger one in the original German, is a valuable addition to our literature, not exactly medical, but scientific. Climatology, however, has many important medical bearings, and its value to the medical man, therefore, ought not to be underrated. The editor has added very largely to the references with the author's consent and has brought the work generally up to date. In fact, while the original work, as we take it, must have been much like the usual German works, deficient in matters more particularly connected with this country, the present volume is very complete in its American references and facts. It is, in fact, much better than the original, and the editor deserves the highest credit for this, though, as he modestly says, he has been careful to obtain Professor Hann's consent to every change that has been made. The work is not only full of information, but the information is in readable form. The remarks on mountain climate are full and complete, and only require a little common sense adaptation to have their value fully recognized from a medical point of view. The work contains a series of tables for the reduction of the metric and other scales to the ones originally used in this country as the metric system is used throughout in the text. The work should be a part of every physician's library.

HYGIENE AND PUBLIC HEALTH. By Louis Parkes, M.D., D.P.H., Lond. Univ., Fellow of the Sanitary Institute, and Henry Kenwood, M.B., D.P.H., F.C.S., Fellow of the Sanitary Institute. With Illustrations. Cloth. Pp. 763. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

This is the second edition of a compendium of hygiene, of which the first was based on an earlier work which ran through some eight or ten editions. The fact that a second edition has been required within a year shows that the book is appreciated. It has been well brought up to date and gives in condensed form the principal points which the student and general practitioner may require.

Miscellany.

Collodium in Treatment of Carbuncle.—Dr. Hauffe of Eilenburg calls attention to the far more rapid healing of a carbuncle when the immediate environment is painted with collodium. The hairs must be carefully shaved off and the center of the lesion treated with sublimate or otherwise as needed. The layer of collodium protects the sound tissues and exerts a gentle pressure, both of which favor rapid repair.—*Allg. Med. Ct.-Ztg.*, lxxii, p. 317.

The fifty-fourth annual session has passed into history. Yes, and with a success and eclat far beyond the most optimistic views of its most sanguine adherents and admirers. From the golden slopes trending toward the Pacific, from Maine, all along the Canada borders, and from the shores of the great lakes, from the extreme Northwest and Southwest, from the great metropoli of the east, Boston, New York and Philadelphia, with swarms from the central and southern states, did come the mighty leaders of the profession with many humbler followers of the healing art, who hope with a commendable pride to be leaders some day, all imbued with one dominant idea—to help, aid and assist their suffering fellow man by adding to, or attaining new ideas, new views, new methods for the relief of suffering humanity. On Thursday morning, between the hours of 10 and 11, in reply to an inquiry, the very efficient and courteous Chairman of the Committee on Registration, Dr. Rudolph Matas, replied, "We have just summed up and find that exactly 2,000 have registered—and here is another," he interpolated, as a registration card, with its accompaniment of $5, was handed over our shoulder. To which we heard an enthusiast near by exclaim, "Johnny on the Spot." That the registration went beyond the 2,000 mark, there were other late comers, and those who had been too busy or negligent to register up to this time, as is always the case, is most gratifying indeed.

This session being held so close to the warm season, on the very edge of the country, in a city, it is true, of over 300,000, yet bounded on one side for many miles by a sparsely inhabited section of our country, as contrasted with other cities in which the Association had met, and on the other by the Gulf—we can but consider the attendance most remarkable, and as a strong

and striking evidence that the method of organization is now on the right road.—*Southern Practitioner.*

State Boards of Registration.

Ohio Report.—Dr. Frank Winders, secretary of the Ohio State Board of Medical Registration and Examination, reports the examination held at Columbus, June 23 to 25, 1903, as follows: Number of subjects examined in, 9; total questions, 90; percentage required to pass, 75; written examination; total number examined, 91; number passed, 83; number failed, 8.

Medical Organization.

Lavaca County (Texas) Medical Association.

This association held a meeting at Hallettsville, July 13. The next meeting will be held in Yoakum in August, when an effort will be made to organize the counties of Lavaca, De Witt and Gonzales into an organization.

Galveston County (Texas) Medical Society.

This society has been organized with quite a large membership. The following officers were elected: Dr. Charles W. Trueheart, president; Dr. Oscar C. Pabst, vice-president, and Dr. Joseph C. Ralston, secretary-treasurer, all of Galveston.

Leon County (Texas) Medical Association.

Physicians of Leon County met at Marquez, July 22, and organized a county association, with an initial membership of 19. Dr. Sam R. Burroughs, Buffalo, was elected president; Dr. William T. Evans, Jewett, vice-president, and Dr. J. H. Joyce, Buffalo, secretary and treasurer.

Yazoo County (Miss.) Medical Society.

Pursuant to a call from Dr. J. Augustus Crisler, councilor for the Fifth District, a number of physicians met at Yazoo City, July 23, and organized a county medical society. The following officers were elected: President, Dr. James P. Moore, Jr., Yazoo City; vice-president, Dr. John Darrington, Yazoo City; secretary and treasurer, Dr. John McCormick, Yazoo City.

Kaufman County (Texas) Medical Association.

This association met at Kaufman, July 14, and organized under the regulations of the state and National associations, with the following officers: Dr. William H. Monday, Terrell, president; Dr. Burrel J. Hubbard, Kaufman, vice-president; Dr. Willis J. Pollard, Kaufman, secretary, and Dr. Delana P. Hicks, Kaufman, treasurer. The next session will be held in Terrell October 13.

Moniteau County (Mo.) Medical Society.

At a regular meeting of the John McDowell (district) Medical Society, which has existed for twenty-five years, held at California, it was decided to disband. After adjournment *sine die*, twelve physicians of Moniteau County met and organized a county medical society, with Dr. John B. Stewart, Clarksburg, president; Dr. Philip Stephens, California, secretary, and Dr. Hugo C. Klueper, California, treasurer. The society will meet August 20 to perfect organization.

Wabasha County (Minn.) Medical Society.

At the thirty-fifth annual meeting, held in Elgin, July 9, it was voted to reorganize the society in conformity with the plan suggested by the American Medical Association. The following offices were elected: Dr. William T. Adams, Elgin, president; Dr. John C. Adams, Lake City, vice-president; Dr. William F. Wilson, Lake City, secretary; Dr. Emery H. Bayley, Lake City, treasurer; Drs. Joseph F. Bond, Wabasha, Jesse A. Slocumb, Plainview, and H. T. McGuigan, Millville, censors, and Dr. William F. Wilson, Lake City, delegate.

Travis County (Texas) Medical Society.

Pursuant to call from Dr. Thomas J. Bennett, Austin, councilor for the Seventh (Austin) District, 36 physicians of Travis County met at Austin, July 18, and organized a county medical society on the plan suggested by the American Medical Association and adopted by the Texas State Medical Association at its last meeting. The following officers were elected: Dr. Benjamin M. Worsham, Austin, president; Dr. Frank a Maxwell, Del Valle, vice-president; Dr. Matthew M. Smith, Austin, secretary-treasurer, and Drs. William T. Richmond, Manor, S. E. Hudson, Austin, and Thomas R. Pettway, Austin, censors.

Grant County (Wis.) Medical Society.

Of the 48 physicians of Grant County who had invitation to a dinner given by Lancaster physicians, July 23, 22 attended, and after dinner the Grant County Medical Society was organized. An informal meeting was held first, of which Dr. James Oettiker, Platteville, was made chairman, and Dr. John A. Gault, Lancaster, secretary. The following officers of the permanent organization were elected: President, Dr. Joseph Godfrey, Lancaster; vice-president, Dr. James Oettiker, Platteville; secretary and treasurer, Dr. Peter L. Scanlan, Lancaster; delegate, Dr. Jonathan C. Betz, Boscobel, and censors, Drs. James M. Lewis, Bloomington, John F. Metcalf, Fennimore, and Guerdon Buck, Platteville. The constitution and by-laws as suggested by the American Medical Association were adopted. The next meeting will be held at Lancaster September 10, when a literary program will be carried out. The place of meeting is to be decided at each meeting, but the time for meetings is the second Thursday of May, September and December of each year.

Societies.

Winnebago County (Iowa) Medical Society.—The annual meeting was held at Forest City, July 22. Dr. Harry R. Irish, Forest City, was elected president; Dr. Ferdinand A. Christensen, Lake Mills, vice-president; Dr. Luther Wall, Thompson, secretary, and Dr. Gissle M. Lee, Thompson, treasurer. The next meeting will be held at Buffalo Center.

Upper Peninsula (Mich.) Medical Society.—The ninth annual meeting was held at Sault Ste. Marie, July 15 and 16. The following officers were elected: Dr. Emil H. Webster, Sault Ste. Marie, president; Drs. Thomas M. Cunningham, Marquette, and C. Frithiof Larson, Crystal Falls, and Dr. S. Edwin Cruse, Iron Mountain, secretary and treasurer. The society will meet next year in Marquette.

Connecticut Members American Medical Association.—The second annual reunion will be held at Savin Rock, August 24. Members are requested to bring their families, and also any eligible candidate for membership in our organization. In order to facilitate the necessary arrangements for the dinner it will be desirable for all who propose to attend to send word before August 18 to the secretary, Dr. James M. Keniston, Middletown, Conn.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Thirteenth Annual Meeting, held at New Orleans, May 4, 1903.

(*Continued from page 330.*)

Revision of Constitution.

Dr. D. A. Thompson, Indianapolis, moved that the majority report be received and that the amendments as suggested be laid on the table. Seconded by Dr. P. Richard Taylor. Motion lost.

Dr. Randolph Winslow, Baltimore, moved that the proposed changes, if adopted, go into effect Jan. 1, 1906. Seconded by Dr. Geo. F. Jenkins.

Dr. A. R. Baker, Cleveland, offered as an amendment to this motion that the time be changed to July 1, 1905. The amendment was accepted by Dr. Winslow and his second and carried.

On motion of Dr. Walker the new Article III as amended by the committee preparing it, was taken up section by section before its final disposition.

Section 1 was read as amended.

Dr. Seneca Egbert, Philadelphia, amended this section by adding after the list of studies:

That certificates from reputable instructors recognized by the superintendents to be hereinafter mentioned may be accepted in lieu of any part of this examination.

On motion of Dr. Walker the section was adopted as amended.

Sections 2, 3, and 4 were then read and adopted as read.

Section 5 was then read. Dr. P. Richard Taylor, Louisville, moved to amend this section as follows: "That at least twelve months shall intervene between the beginning of any course and the beginning of the preceding course" be stricken out. Seconded by Dr. W. A. Evans, Chicago. Motion was lost. (Nays, 21; yeas, 11.)

On motion Section 5 was adopted as originally read.

Section 6 was read.

Dr. Randolph Winslow, Baltimore, moved to strike out:

Credit for full year of time may be given students holding the degree of A.B., B.S. or other equivalent from a reputable university or literary college.

Seconded by Dr. David Streett.

Dr. H. B. Ward, Lincoln, Neb., offered the following amendment to the amendment:

To add to Section 6, "Provided such degree represents not less than 900 hours of definite premedical work in laboratory science."

Seconded. The amendment was lost. (Nays, 22; yeas, 9.)

Dr. J. M. Dodson, Chicago, offered the following amendment to this section:

Credit may be given to the holder of a bachelor's degree from a reputable college or university for any work in the medical branches which he has successfully completed in his college course, and that is the full equivalent of corresponding work in the medical curriculum. Such student may be allowed to complete the course for the medical degree in not less than thirty-one (31) months, provided he completes the remainder of the medical curriculum in that time.

Seconded and carried.

On motion Section 6 was adopted as amended.

Section 7 was read and adopted as read.

On motion of Dr. Dodson Article III was adopted in its entirety.

The chair appointed the following nominating committee: Drs. Wm. J. Means, R. Winslow and T. J. Hawkins.

On motion, the Association adjourned until 8 p. m.

Evening Session.

The Association reassembled at 8 p. m., and was called to order by the president.

The report of the secretary-treasurer was called for and read, and, on motion of Dr. Wathen, was accepted as read.

Report of Judicial Council.

Dr. Wm. J. Means, chairman of the judicial council, reported as follows:

Mr. President, Members and Delegates of the Association of American Medical Colleges:

The report of the judicial council for the last year will necessarily be brief. Aside from the correspondence of the chairman and the disposition of applications for membership in the Association from a number of colleges, only one important matter came before the committee for adjustment.

Communications were received from a number of colleges of the Association and from other sources asking information on the eligibility of students to certain standing and for a construction of particular paragraphs of the constitution and by-laws. The chairman assumed the responsibility of replying to these communications without submission to the other members of the council. His opinion seemed to be satisfactory in every instance, therefore further submission of the inquiries was unnecessary.

There were a few complaints of irregularities against colleges of the Association, but inasmuch as they were not filed regularly they were not considered.

The year as a whole has been a very satisfactory one. Judging from the tenor of the communications from the officials of the different colleges, it is the opinion of the chairman that an honest effort is being made to comply with the rules of the Association and that commendable work is being done toward a higher standard in medical education

Entrance qualifications and time requirements are matters that come to the judicial council more than any others for adjudication. Fortunately for the Association a number of states by legal enactment have fixed the academic qualification for students and also the time requirements for a medical course. In a few of these states the right to examine applicants as to their literary qualifications for entering a medical college has been taken away from the college faculties and placed in the hands of examiners appointed by the state board. This is a step in the right direction. It will do more to raise the standard of preparatory education than anything else.

Through the efforts of the National Confederation of State Medical Examining Boards and the profession at large, every year adds other states to this list. With the present tendency it looks as though the day was not far distant when there will be uniform standards and reciprocity among the various states in the Union. Then the purpose of the College Association will be as it should be, purely educational, and the work of the judicial council perfunctory. Under the present conditions the Association is in an anomalous position. Owing to the low standard of entrance requirements and short terms, the diplomas of a large number of colleges, members of the Association, are not recognized in several states. It is, therefore, impossible for the medical colleges in these states to recognize the credentials of their fellow members. This condition of affairs should not obtain.

The charges preferred against the Milwaukee Medical College at the last session of the Association were taken up, and by mutual consent of the parties interested, Dr. R. O. Beard, secretary of the faculty of the University of Minnesota, was selected to make the examination. His expenses were paid by the accused college.

He made a thorough investigation and submitted the testimony in detail, and his finding thereon to the chairman of the judicial council. The testimony and Dr. Beard's report were submitted to Drs. Ritchie, Dodson, Griffith, Hawkins and Means. Dr. Welch, elected a member of the judicial council at the meeting in Saratoga, refused to serve. The proceedings were not sent to Dr. Keen of Philadelphia. The five members above mentioned, after examining the testimony, voted unanimously to sustain the findings of Dr. Beard. Said report is herewith submitted for your consideration.

REPORT OF SPECIALLY APPOINTED COMMISSION.—R. O. BEARD.

"The undersigned begs to report (1) that at the instance of your body he conducted at Milwaukee, Wis., on July 15, 16 and 17, 1902, an investigation into the charges preferred by the Milwaukee County Medical Society against the Milwaukee Medical College.

(2) That these charges were revised at the opening of the investigation; that by request of the preferrer the charge respecting the conduct of unwarrantable obstetrical demonstrations was withdrawn; that by the decision of your investigator, the charges covered by specifications 4 and 5, as originally stated, were ruled out, on the ground that they did not involve any issue pertinent to the rules of the Association, unless it could be shown that the Milwaukee Medical College was prejudiced educationally by its financial ownership and control; and that if it were so prejudiced educationally, that fact would in itself disqualify its membership in the Association without reference to its financial status.

The charges, as revised, by consent of both parties to the investigation, are as follows:

CHARGE I.

The Milwaukee Medical College does not require sufficient preliminary education of applicants, as a requirement for admission to its courses.

It admits students without preliminary training, thus violating the standard laid down by the statutes of the State of Wisconsin and the National Association of American Medical Colleges.

The institution gives credit so as to entitle students to advanced standing without presenting the necessary educational credentials for such credit.

CHARGE II.

The Milwaukee Medical College has violated the medical laws of this state in that it does not give the required courses of study as far as time devoted thereto is concerned.

The catalogue of the College advertises two or more courses of fourteen weeks each in one year, and states that credit is given for one year's work on completing two terms, thus enabling students to complete a course of four years in less than three.

The college advertises courses of lectures by professors who are not and were not connected with the institution, and did not give the lectures advertised.

The college allowed one man to fill four or five chairs, thus not having a complete faculty as advertised.

The Milwaukee Medical College during the past year has had no adequate course in anatomy.

The college is not giving the educational examinations on entrance to the course of study.

CHARGE III.

The Milwaukee Medical College has granted diplomas to persons unfit both from an educational and moral standpoint to practice medicine.

The college has granted diplomas to students who failed to pass the requisite examinations.

The Milwaukee Medical College allowed men to practice medicine before completing their course and receiving their diplomas.

(3) That exception was taken by the defendant college to the charges, on the score of their alleged non-specific character. Your investigator ruled in favor of the adequacy of the charges, provided they were specifically sustained by evidence.

That your representative ruled that evidence tending merely to show infraction of the laws of the state of Wisconsin was incompetent, since the rules of the Association are not coincident with or dependent on the statutes of any state; that such evidence could only possess a secondary value as corroborative of proof that the defendant was in violation of the Association rules.

That he further excluded all evidence tending simply to show personal bias or local prejudice in either party and required that evidence to be acceptable should deal only with questions of fact, or of professional opinion of the facts based on sufficient experience in the premises.

(4) That the following are his findings on the several charges, based, in his judgment, on the evidence submitted and the records of the Milwaukee Medical College:

(I) The charge that the Milwaukee Medical College has admitted students to its courses without the preliminary education required by the rules of the Association is sustained:

(A) In that the college has accepted inadequate credentials in proof of such education.

(B) In that it has admitted students unpossessed of such credentials without submitting them to the examination required by the rules of the Association.

The further charge that it has admitted students to advanced standing whose credentials did not entitle them to the same, is sustained.

(II) The charge that the Milwaukee Medical College has not required its students to fulfill the four years' course of study, each year to represent a period of not less than six months, no two of which periods shall be taken in the same year, is sustained by the evidence and by the published announcement of the college, 1901-02, page 16.

The charge that the college has advertised the employment of professors who were not connected with the institution is technically sustained, but is traceable to circumstances which the college could not at the time control.

The charge that the college allowed one man to fill several chairs at one time is sustained by the facts; this course being, however, in the judgment of your investigator, an unwise method of filling certain vacancies in the faculty for which the college was not initially responsible.

The charge that the college has had during the past year incomplete and deficient facilities for the study of anatomy is sustained, at least so far as a part of the year is concerned.

The charge that thorough or adequate examinations are not given by the college on entrance to a course of study, is sustained so far as entrance examinations are concerned, but rests on hearsay and contradictory evidence, and is not, in the judgment of your investigator, proven so far as its professional examinations are concerned.

(III) The charge that the Milwaukee Medical College has granted its diploma to persons notoriously unfit, both from an educational and moral standpoint, is sustained on the question of educational unfitness. There is no evidence to show that the college was aware of any moral unfitness in its graduates, although it does not appear to have concerned itself to ascertain their moral status.

The charge that the college has given its diploma to students who failed to pass the requisite examinations is sustained in the fact that it has permitted certain students to substitute for otherwise unremoved conditions, altogether inadequate courses of study. Its rating for the passing of students in all branches has been unfortunately low.

The charge that the college has allowed students to practice medicine before completing their course and receiving their diploma is not sustained since the college has the power neither to permit nor to prevent such illegal practice. It has undoubtedly permitted students to leave the college and abandon study before they had completed the course required by the rules of the Association, although the evidence shows that the college sought to correct this error during the last term of 1902 by its recalling its students.

Your investigator does not deem it any part of his duty in the premises to recommend any action on this report, either by the Association or its judicial council. Respectfully submitted,

[Signed.] R. O. BEARD, M.D.

Minneapolis.

NOTE.—The evidence given at the investigation of the Milwaukee Medical College by the Wisconsin State Board of Medical Examiners was made by consent the basis of this investigation and the testimony therein given by each witness was read and substantiated or amended by him and used as a foundation for further examination. This previous evidence is therefore embodied in this report.

By personal request of Dr. W. H. Earles of the Milwaukee Medical College, affidavits are introduced in counteraction of evidence given regarding his attitude toward the Wisconsin Medical Practice Act, although such evidence is not regarded by your investigator as pertinent or relevant to this issue."

Application for membership was made by the College of Physicians and Surgeons at Kansas City, Kans. A thorough and impartial examination was made of the facilities of the college, its curriculum and requirements. The former were found quite limited, and judging from information derived from various sources, its requirements are below those of the Association. The council, therefore, recommended the rejection of the application.

Application for membership was made by the University of Missouri situated at Columbia, Mo. The council recommends recognition of the medical department of said university for the first and second years of a medical course, but inasmuch as the clinical facilities must necessarily be limited in a city of the size of Columbia, it is thought best to withhold recognition and membership for the third and fourth years until the college can demonstrate ample clinical facilities for these years.

Application for membership was made by the medical department of the University of Tennessee situated at Jackson. The council recommends that action be deferred until the college can be investigated, and that the investigation be referred to Dr. Means.

Application for membership was received from the Memphis Medical College, but was later withdrawn.

Application from the University of West Virginia at Morgantown for recognition and membership of the first two years of a medical course was received and the council advises that action be deferred until an investigation can be made. The matter was referred to Dr. Dodson for investigation.

Application of Bucknell University of Pennsylvania made at the last annual meeting, referred to Dr. Keen of Philadelphia, was withdrawn.

Application for membership was received from the Dallas Medical College, Dallas, Texas. The council advises that action be deferred until the next annual meeting, and that Dr. J. D. Griffith of Kansas City, Mo., be requested to investigate the college.

Application was received for membership from Wake Forest College, at Wake Forest, North Carolina. The council advises that action be deferred and that Dr. Winslow of Baltimore be requested to examine into the merits of the college.

An application for membership was received from the University of Mississippi located at Jackson. The council asks for further time to investigate the college, and has referred the application to Dr. Means.

This concludes the report of the judicial council. We thank the official members of the Association for their kindly assistance in the work brought before them.

[Signed.] W. J. MEANS, Chairman.
J. M. DODSON,
H. B. WARD,
R. WINSLOW,
T. H. HAWKINS.

Dr. W. A. Evans, Chicago, moved that the report of the judicial council be accepted and that the Milwaukee Medical College be censured. Seconded by Dr. A. H. Levings.

Carried.

Dr. W. H. Earles, dean of the Milwaukee Medical College, expressed his thanks on behalf of his college for the leniency of the Association.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Medicinal Treatment of Hyperchlorhydria.

A. A. Jones, in the *Internat. Med. Magazine,* states that in considering the treatment of hyperchlorhydria the following conditions must be corrected: 1. The excessive acidity. 2. Constipation. 3. The pain which comes on at the height of digestion. He states that in the majority of the cases of hyperchlorhydria the following powder gives prompt relief:

℞.	Cerii oxalatis	3i	4
	Bismuthi subcarb.	3ii	8
	Magnes. carb. levis.	3iv	16

M. Sig.: From one-quarter to a heaping teaspoonful stirred in a quarter of a glass of water, to be taken two hours after each meal.

If pain and constipation persist extra doses should be administered. He advises against the administration of alkalies before meals, unless there is co-existing atony. In his experience a combination of potassium bicarbonate, sodium bicarbonate, and sodium and potassium tartrate are very effectual in the treatment of hyperchlorhydria, especially when there is constipation present, accompanied by drowsiness and headache. These preparations may be combined in the following proportions:

℞.	Potass. bicarb.	3ii	8
	Sodii bicarb.	3iv	16
	Sod. et potass. tartratis	℥i	30

M. Sig.: One even teaspoonful dissolved in water at 10 a. m., 4 p. m., and 9 p. m.

The alkaline and saline waters are of service, such as the Vichy and Carlsbad waters.

The bromids, given in 10-gr. (.60) doses after meals, diminish the secretion of the hydrochloric acid through their influence on the nervous system.

Locally silver nitrate produces the best effects, administered in the form of a douche or intragastric spray in the strength of 1 to 1,000. Chloretone is also mentioned by the author as of service in allaying the burning distress and pain, given in 5-gr. (.30) doses night and morning. As an adjuvant treatment, to relieve the pain, the following combination is recommended:

℞.	Cocainæ muriatis	gr. ss	03
	Acidi hydrocyanici dil.	gtt. v	30
	Aquæ laurocerosi	3ss	2

M. Sig.: At one dose, to be repeated if necessary to relieve the pain.

Ringworm.

In the treatment of ringworm appearing on the body, the following, according to *Merck's Archives,* is of service:

℞.	Naphthol (resublim.)	3ss	2
	Olei picis liquidæ	3ss	2
	Sulphuris	3i	4
	Lanolini	3v	20

M. Ft. unguentum. Sig.: Apply locally night and morning; or:

℞.	Chrysarobin	gr. xl	2 65
	Ichthyol	3i	4
	Acidi salicylici	gr. xv	1
	Ol. petrolati	℥ss	15
	Lanolini	℥i	30

M Ft. unguentum. Sig.: Apply locally twice daily.

The iodin preparations are frequently employed to destroy the parasite. They may be combined as follows:

℞.	Iodi	5ss	2
	Potassii iodidi	gr. xv	1
	Alcoholis	3ii	8
	Aquæ	℥ss	15

M. Sig.: Apply locally twice daily by means of a brush.

J. Nevins Hyde recommends some of the simpler remedies as serviceable in the treatment of ringworm of the body:

℞.	Lac. sulphur.	3iiss	10
	Spts. saponis viridis		
	Tinct. lavendulæ, āā	3vi	24
	Glycerini	3ss	2

M. Sig.: To be applied locally; or:

℞.	Iodi (pure)	℥i	30
	Olei picis liq. (sp. gr. .853)	℥ss	15

M. (These preparations should be mixed with care gradually.) Sig.: Apply locally; or:

℞.	Creosoti	m. xx	1 30
	Olei codini	3iii	12
	Sulphuris precip.	3iii	12
	Potassii bicarb.	3i	4
	Adipis	℥i	30

M. Sig.: To be used locally in obstinate cases of ringworm of the adult.

Night-sweats.

Ladisl, according to an abstract in *Amer. Med.,* considers gua-camphol the best remedy in checking night-sweats. It should be given in 3 to 5 gr. doses (.20-.30) and continued over a period of two weeks. This preparation is insoluble in an acid medium, but breaks up into guaiacol and camphoric acid when reaching an alkaline medium in the intestine.

Acute Articular Rheumatism.

The *N. Y. Med. Times* recommends the following outline of treatment in acute rheumatism:

℞.	Sodii iodidi	3ii	8
	Sodii salicylatis	3iii	12
	Syr. sarsap. comp.	℥iii	90

M. Sig.: One teaspoonful after each meal in water.

Locally the following:

℞.	Olei gaultheriæ	℥ss	15
	Linimenti chloroformi	℥iss	45

M. Ft. linimentum. Sig.: To be applied locally night and morning.

As a combined alkaline and salicylate mixture the following may be given, which is according to the formula of Whitla:

℞.	Sodii salicylatis	3iv	15
	Potassii bicarb.	3v	20
	Liq. morphinæ hydrochloridi (1 per cent.)	3i	4
	Aquæ camphoræ q. s. ad	℥viii	240

M. Sig.: One tablespoonful four times a day in one-half a glass of water.

Furuncles.

M. Cohn, in *Monat. Pract. Dermat.,* recommends the following combination as a very efficient local remedy in the treatment of boils:

℞.	Ichthargin	3i-iiss	4.-10
	Aq. destil.	3i	4
	Glycerini	3iiss	10
	Ol. petrolati	℥i	30
	Lani	℥iss	45

M. Ft. unguentum. Sig.: Apply locally around the boil and over it.

The inflammation, according to the author, subsides in a short time, when the ointment may be replaced by a 1 per cent. ichthyol ointment.

To abort furuncles, pure carbolic acid introduced into the center of the inflamed area is of value. It may be applied in this way by simply dipping a sharp toothpick made of hard wood into the pure solution, and by rotating it and applying gentle pressure it will penetrate the skin without any pain, as the carbolic acid will act as a local anesthetic.

The following combination applied topically has been employed to abort furuncles:

℞.	Europhen	3i	4
	Olei olivæ	3ii	8
	Lanolini		
	Ol. petrolati, āā	3v	20

M. Sig.: Apply locally and cover the area with sterilized gauze.

Sodium Cacodylate.

The following combinations containing sodium cacodylate are recommended by *Bul. Gen. de Ther.* Where it is necessary to prevent disturbance of the digestive tract the following may be administered hypodermically:

℞. Sodii cacodylatis .....gr. c 6 | 65
Liq. acidi carbolici .....gtt. x | 65
Aquæ destil. .....ʒiiiss 105

M. Sig.: Fifteen drops to be injected once or twice daily.

As a rectal injection the following solution may be employed:

℞. Sodii cacodylatis .....gr. iii-vi | 20-.40
Aquæ destil .....ʒvi 180

M. Sig.: At one dose introduced per rectum and retained. Two injections may be given daily for six days, three daily for ten days. The remedy should be stopped then for three days and repeated as before.

In the treatment of skin diseases it is of value given internally in the pill form:

℞. Sodii cacodylatis .....gr. iss | 09
Extracti gentianæ .....gr. i | 06

M. Ft. pilula No. i. Sig.: One such three times a day after each meal; or in the form of a mixture as follows:

℞. Sodii cacodylatis 3ss 2
Spts. frumenti 3vss 22
Syr. simplicis 3iv 15
Ol. menth. pip. .....gtt. ii | 12
Aquæ destil. .....ʒii 60

M. Sig.: One teaspoonful in water after each meal.

Summer Diarrheas in Children.

Leo Ratner, in *Merck's Archives*, states that the treatment of summer diarrheas, as of all gastrointestinal trouble, may be divided into hygienic, dietetic and medicinal. He quotes several formulæ, recommended by Winter, for the home modification of bottled milk. Beginning with a formula suited to an infant one week old this formula is changed to suit the age and needs of the infant until the ninth month.

As to the medicinal treatment, he recommends the usual employment of small doses of calomel as the initial medication followed by intestinal astringents. He is averse to the employment of toxic preparations such as resorcin and naphthalin as they tend to lower the vitality of the infant.

He favors the use of tannalbin and ichthalbin as follows:

℞. Tannalbin 3ii 8
Ichthalbin 3i 4
Pulv. cinnamomi .....gr. vi | 40

M. Ft. chart. No. xxiv. Sig.: One or two powders at one dose, according to the age, and repeated three to six times a day; or:

℞. Tannalbin 3i 4
Bismuthi subnit. 3i 4
Magnesiæ (calcined) 3ss 2

M. Ft. chartulæ No. xii. Sig.: One powder every three hours; or:

℞. Tannalbin 3ii 8
Bismuthi subnit. 3ii 8
Mist. cretæ .....ʒiii 90

M. Sig.: Shake the bottle. One teaspoonful every three to six hours; or:

℞. Tannalbin
Ichthalbin
Bismuthi subnit., āā.....3i 4
Tinct. opii camph. 3iv 15
Syr. rubi ideai .....ʒi 30
Aquæ q. s. ad.....ʒiii 90

M. Sig.: Shake. One teaspoonful every one or two hours; or:

℞. Tannalbini .....gr. xx 1 | 30
Ichthalbini .....gr. x | 65
Tinct. opii .....m. ii | 12
Aquæ amyli .....ʒii 60

M. Sig.: Shake. At one dose per rectum. The author, as noted in the foregoing, uses opium in some of the combinations, which is, in his opinion, of great value, after thoroughly emptying the bowel, but he condemns its use before the putrid contents are removed.

Ointment of Adrenalin.

M. Mignon, in *Scm. Méd.*, recommends an ointment of adrenalin rather than the aqueous solution in relieving the congestion and swelling of the turbinated bodies. He employs the following combination for local application:

℞. Adrenalin .....gr. ss | 03
Olei geranii .....gtt. iii | 20
Olei petrolati 3iii 12
Lanolini 3iv 15

M. Ft. unguentum. Sig.: To be applied freely to the nares with an applicator.

Although this ointment is slower in its action than the 1:1000 aqueous solution, the effects last much longer. He recommends it in acute congestions of the nasal mucous membranes and to prevent secondary congestions after cauterizations.

Medicolegal.

Delirium Resulting from Illness.—The Court of Appeals of Kentucky holds, in Supreme Lodge Knights of Honor vs. Lapp's Administratrix, that where a person was suffering from violent pains in the head, which had continued for some time, and seemed to be wandering and distrait, there was at least ground for the conclusion that he was suffering from delirium resulting from illness. And there being no other reason shown for his committing suicide, it holds that the question of whether he committed it in delirium resulting from illness was properly left to the jury, under a benefit certificate which provided that the order would not pay the benefits of those members who committed suicide, whether sane or insane, except it be committed in a delirium resulting from illness, etc. It would be an extension of contract, the court holds, to say the word "illness" referred only to such a sickness as confined the insured in bed.

Asking About Views of Others—Cross-Examination.—The Supreme Judicial Court of Massachusetts holds, in the personal injury case of Root vs. the Boston Elevated Railway Company, that a medical witness was not called on to say what the views of other surgeons might be, or as an expert to determine whether medical men would not differ in opinion when asked about the effect on the health of the individual of certain physical conditions. It appearing that the party suing did not call as a witness a physician, who, previously to the trial, at her request, made an examination of her physical condition, and that the company then called him, the court says that it might be inferred that his testimony was not wholly favorable to her contention as to the extent of her injuries, and that it was proper to ask him on cross-examination as to how far he required from a patient a full disclosure of symptoms and history of the case. This, it says, would be necessary to furnish data on which to base an opinion. And it holds that it could not be said that the further question as to whether he disclosed the information thus obtained to other persons was outside the limits of a reasonable cross-examination.

Responsibility of Patient in Personal Injury Case.—The Supreme Court of Missouri, Division No. 2, says in the personal injury case of Elliott vs. Kansas City that the question with which it was confronted was whether a person who has been injured by the negligence of another and who employs a reputable physician to treat him for the injury, is responsible for the mistakes and errors of judgment of the physician, and also, if he is told by his physician that no futher treatment is necessary, is he responsible if he could have been benefited by medical treatment? In its answer it says that it seems, both on reason and authority, that when a person is injured by the negligence of another he is bound to use ordinary care to the end of his restoration or cure, and is not responsible for the mistakes of an attending physician, and when he acts in good faith under the direction of such physician any mistake of the latter in the treatment will not absolve the party whose negligence caused the injury from liability in damages therefor. And it holds that, while the party suing in this case was not entitled to recover damages for such conditions as were entirely due to her previous injury or disease, if any such state

of facts existed, she was entitled to have considered by the jury, in estimating her damages, any injury that may have been caused by improper medical treatment.

Evidence and Award in Compound Fracture Malpractice Case.—The Supreme Court of Nebraska holds, on the appeal of Leisenring vs. La Croix, that, in an action against a physician and surgeon for alleged negligent treatment of a compound fracture of the bone, it is permissible to show by another surgeon what would be the proper treatment for a simple fracture, and that the treatment for a compound fracture would not be materially different. In such an action it is proper to submit evidence relating to the condition of the patient's health at the time the treatment began, and also the length of time he was treated by others after the physician sued ceased to attend him, the jury being cautioned to compensate him only for such injury and damage as may have been caused by reason of the negligence of the physician sued. Where there was evidence that under proper treatment the fractured bone should have united within six weeks, and that the patient was confined under the physician's treatment for a period of fourteen weeks, most of the time in great pain, it was proper to submit to the jury the question whether the pain and suffering was caused by the physician's negligence, and to authorize a recovery therefor. A verdict for $1,140 in such a case, where the compound fracture was of the tibia and fibula of the right leg about three inches above the ankle, is upheld, when corrected by a remission of an item of interest erroneously allowed between the date of the injury and that of the judgment.

Liability of Hospital Patient for Medical Treatment.—The Supreme Court of Michigan says, in the case of Crumrine vs. Austin, that the latter being ill, his physician advised his brother that he had better go to a hospital. At the suggestion of the patient or his broher, the physician had a conversation with some one at the hospital by telephone, and was told by him that it would cost $15 a week for a private ward, and that would include room, board, nursing, and medical attendance, and that he communicated this to the patient. On cross-examination, however, the physician qualified the above statement, made on his direct examination, by stating that he was told over the telephone that the price included the attendance of a house physician and nursing, and that nothing was said about an operation. Nothing in the testimony indicated that the nature of the illness was mentioned in the conversation by telephone. The patient was removed to the hospital, where he remained several weeks. He was operated on by the physician bringing this action, who was called by the house physician, and who rendered him daily service by dressing his wound for a time. When the house physician did so on one occasion, the patient objected, and expressed a preference that the physician suing should continue to dress his wound, and a willingness to pay extra if he would, and the physician suing performed that service thereafter. The patient paid the hospital the sum of $15 per week in advance, but was surprised to receive a bill from the physician suing of $200 for the operation, and a total of $167 for other attention. The physician testified that the price charged was reasonable, unless it be considered qualified by the statement that the charge in such cases depends on the ability to pay, and his conversation with the patient, from which it might be inferred that physicians "regulate their fees by the financial standing of their patients," and that "persons who have political jobs are made to pay for cases where doctors work for nothing," which the patient stated that the physician suing told him, and the physician denied. The case was left to the jury, and a verdict was found of $99 for the physician, who thereafter appealed. The Supreme Court says that the verdict indicated that the jury must have found that the contract was as claimed by the patient, namely, to include the cost of the operation in the price given of $15 per week. The physician who telephoned for him was his agent, and neither the hospital nor the physician suing was bound by any misapprehension on the part of the physician who telephoned, or misunderstanding growing out of his inaccurate report to the patient of the terms offered. We must conclude from the undisputed testimony that the attendance of a house surgeon only was offered, and that neither party spoke of an operation. There was nothing to indicate that the hospital authority who talked with the telephoning physician had any reason to suppose an operation was contemplated, and, if that physician had one in contemplation, it was not mentioned. He asked for the house surgeon, and it was reasonable to suppose he knew the duties of such an officer; also that his patient would be expected to enter the hospital subject to its rules, whatever they were, except as they might be modified or affected by the conversation. A by-law introduced showed that the house surgeon was not given charge of patients. The trial court could properly have said that the contract was not proved as claimed by the patient. He would then be liable for the reasonable value of the services rendered. The physician suing was injured by an instruction which permitted the jury to exclude the value of the operation and early attention from the sum allowed. On the other hand, the reasonable value of the services was a question for the jury.

1 The Shattuck Lecture Before the Massachusetts Medical Society, June 9, 1903: The Sources, Favoring Conditions and Prophylaxis of Malaria in Temperate Climates, with Special Reference to Massachusetts. Theobald Smith.
2 *Studies on the Action of Alcohol in Disease, Especially on the Circulation. Richard C. Cabot.

2. **Alcohol.**—Cabot studies the effects of alcohol in disease, taking special care to be unaffected by any prejudices he may have had in his method of study. He reviews the known facts of the effects of alcoholism on tissue change, digestion, absorption, diuresis, diaphoresis, respiration, circulation, blood pressure, etc. He notices also the tolerance of febrile patients for alcohol, and the psychic effects, both on the patient and the physician. He summarizes his conclusions in the following:

1. In 41 patients, mostly cases of typhoid fever, 1,105 measurements of the blood pressure were made before, during and after the administration of alcohol in therapeutic doses. Neither the maximum nor the minimum blood pressure showed any variations that could reasonably be referred to the action of the alcohol. So far as was determined by the methods and in the cases used in this research, the action of alcohol on the circulation was nil. 2. The same neutrality and apparent inertness of therapeutic doses of alcohol in relation to the temperature, pulse rate, respiration rate, appetite, sleep, delirium and secretions (renal and cutaneous) of 309 patients suffering from a great variety of diseases was the total impression derived from 2,160 observations in these cases. 3. These observations are not interpreted as proving that alcohol is useless or useful in disease. As a narcotic and vaso-dilator it may have an important place in therapeutics. 4. More important probably than any of the questions investigated so far is the problem of the effect of alcohol on the power of the sick man's blood to protect him against infection and other harmful influences. The studies of Abbott and of Mircoli have begun to clear a path in this direction, and we have a certain amount of evidence relative to a similar problem in the lower animals. But as the results of studies regarding the action of alcohol on animals or on healthy men can not be used as evidence of its action in sick men, there is a good field for experimental work in this direction along the lines of Ehrlich's newer methods.

5 *The Pathology of Latent Malarial Infection as Observed at Autopsy. Charles F. Craig.
6 *Fowler's Position in Abdominal Surgery. Van Buren Knott.
7 *The Diagnosis and Treatment of Inflammation of the Accessory Nasal Sinuses. Joseph S. Gibb.

3. **Mycotic Enzymes.**—Buxton's article elaborately details the physiologic action of ferments. He gives tables at the end of the bacteriologic species producing enzymes hydrating carbohydrates, and of the corresponding proteolytic enzymes digesting milk, gelatin, fibrin, etc.

4. **Tumors of the Breast.**—McGraw notices the different forms of breast tumors, and considers that many cases are not necessarily malignant. The benign swellings even in the climacteric period are much more common than is usually supposed. He

notices the different forms of milk cyst, the fibrous tumors, and the serous cysts. He identifies the latter largely by the use of the exploring needle, and would feel lost without the aid it gives. He notices, however, some diagnostic mistakes in his own experience. When the evacuation of the cyst contents does not cause an entire disappearance of the swelling but leaves behind a hardened lump, the pathologic condition may give considerable anxiety and trouble. He considers it then the proper time for an exploratory incision. He says in conclusion:

No breast ought to be adjudged cancerous without the most thorough examination by all possible methods, but when the surgeon, using his best judgment after full investigation, has come to the conclusion that he has to deal with a tumor of dangerous tendencies he should then operate on it so thoroughly as to destroy if possible every secondary growth, whether in fascia or muscle, skin or gland. He should assume that the skin above it, the fascia and muscle below and all of the neighboring lymphatic vessels and glands are already infected and should make the operation wide enough and deep enough to take in all of the suspected territory.

We can not as yet say that we can in this way cure all patients with the disease, nor even a majority of them, but we may truthfully claim to have had a success in a very large minority—which our predecessors in surgery never achieved.

I have now many patients who are living without recurrences after three, five, and ten years, and feel justified therefore, in spite of many discouraging failures, in recommending the operation as the only treatment which as yet has shown a fair measure of success.

Above all things, we should try to keep our patients out of the hands of the charlatans, who inflict on them indescribable tortures which in the very nature of things can not possibly be of service.

5.—See THE JOURNAL, July 11, p. 125.

6.—Ibid., Jan. 10, 1903, p. 118.

7. **Nasal Sinuses.**—Gibbs finds from his experience that in the acute form of nasal sinusitis, the ethmoid is most frequently involved, the next in frequency being the frontal. Acute sinusitis varies in intensity in great degree, and is usually unilateral, therefore the presence of a one-sided purulent discharge from the nose should excite suspicion. It is in the acute form that early recognition and prompt treatment are most important, and the object should be to obtain free drainage. It is usually a self-limiting process and if we keep the natural outlets free, it will greatly aid. In the use of vasoconstrictor drugs, we can do much to reduce the size of the cavernous tissue and keep open the various natural outlets. Some of the more severe cases may resist this plan, and may require a prompt and thorough evacuation of the pus contents. Of the chronic forms of sinusitis, the antral is most common, next, the frontal, and here a careful diagnosis is the first essential. He details the diagnostic points at length of the antral sinus inflammation. Transillumination is not infallible; amount of discharge and pain are only assistants to diagnosis. Failing to get at the diagnosis by other methods, we have a measure always to be left to the last, but which may combine both diagnostic and therapeutic values; that is, puncture of the antrum through the inferior meatus. The treatment is entirely surgical, but this puncture alone may, in many cases, be all that is required. He remarks, however, as to the use of more radical methods, especially that of Jensen, of opening through the canine fossa and making a flap of the nasal wall of the sinus, which is turned up and subsequently adjusted. Ethmoid sinusitis is noted also at some length. According to his personal experience the chief things in treatment are free drainage and thorough irrigation, and the operations of opening the sinus both by the open and closed method are described. Ethmoid sinusitis, if uncomplicated, is more amenable to treatment than either of the other varieties; but it is seldom altogether uncomplicated. The symptoms are much the same as those of the other types, only the obstruction and pain are usually more prominent and pronounced. There is a form of ethmoiditis occasionally met with, in which the inflammation is largely confined to the middle turbinate. It is a question whether it belongs to the type of disease under discussion, or is only a local expression of a constitutional condition, such as syphilis, tuberculosis, etc. The treatment consists simply in removing the hypertrophied turbinate by a cold wire snare, and treating antiseptically. Sphenoid sinusitis is the more difficult to treat, and requires more care in the operative management, on account of the important parts closely contiguous, but his remarks on this subject are comparatively brief.

11 *Alcoholic Toxemia; Its Pathology and Treatment. Thomas D. Crothers.
12 Infant Feeding. A Science and Art. John F. Connors.
13 A Case of Panophthalmitis in Typhoid Fever. W. Whitehead Gilfillan.

9. **Malignant Tumors of the Testis.**—These, according to Coley, are much more likely to be sarcoma than carcinoma. They also, contrary to Butlin, are not infrequent in young adult life, between 20 and 30. As a cause, trauma plays a very prominent part. The diagnosis is not usually difficult, tuberculosis of the organ most closely simulating the condition. In sarcoma the tumor is of a uniform consistence, the reverse of which is the case in tuberculosis, the epididymis being harder than the testis proper. Coley does not agree with Kober as to the favorable outcome of these cases, but admits that most of those he has seen were not in the early stages where treatment might be expected to be most effective. The rapid course of the disease is somewhat notable, sarcoma being more early fatal here than in other parts, as a rule. The treatment, he holds, consists in the complete removal of the testis and cord as high up as the internal ring, as soon as the diagnosis is made. In addition, he would advise treatment with mixed toxin serums. The prognosis of teratoma is good, though recurrences and metastases do sometimes occur. He reports a number of cases illustrating the types.

10. **Alcoholism in Women.**—The danger of prescribing alcohol to women, and of secret drinking on their part, are noticed by Sparks, who reports a case. The risk, she says, of prescribing even beer, is large.

11. **Alcoholic Toxemia.**—Crothers notices the action of alcohol, and discusses the treatment of alcoholism. In delirium tremens, he believes in the early and complete cutting off of all stimulants, and the use of the absolute essentials—sharp purgation, and sweating. The best results follow the elimination by this double process. In addition, he speaks well of chloretone for the drug treatment. He has not noticed any cumulative action, and its hypnotic effect is rapid; nor does it seem to cause any disturbance of digestion, nor have any bad effect following its use. After-treatment should be salines and baths, the latter daily, together with bitter tonics. Arsenic is a valuable remedy, and also some preparations of phosphoric acid.

July 25.

14 *Some Cases Treated by the X-Ray. William James Morton.
15 *Congenital Laryngeal Stridor. James E. Newcomb.
16 *Perichondritis of the Larynx, with a Report of a Case. Emil Mayer.
17 Gouty Phlebitis. A. A. Getman and R. W. Amidon.
18 *Hybrid Malaria. J. Lindsay Porteous.
19 *Authority and Facts. J. R. Clemens.

14. **X-Ray Treatment.**—Morton gives the results of *x*-ray treatment in a variety of affections, including facial cancer, carbuncle, cheloid, acne, alopecia areata, sychosis, fibroid tumor, psoriasis and lupus. He has had good results in the latter affection from the use of a method with a lead shield arranged so as to expose one-half an inch of normal skin around the edges of the lupus, and treating with the *x*-ray three times a week until the sound skin presented an angry purplish red *x*-ray dermatitis, while the lupus itself began to appear swollen, angry, red, exuding serum, and elevated. Using the normal skin as a control and a guide, he has found that the lupus after stoppage of treatment at the stage mentioned, went on to a complete cure by itself; and the skin previously occupied with the disease is now natural. He now treats all cases of lupus with this plan of using the sound skin as a control, and finds it more successful than either milder or more excessive methods.

15. **Congenital Laryngeal Stridor.**—This condition Newcomb describes and states that it predominates in male babies, though

the reason for this is not given. He points out the diagnostic points and discusses the theories. He thinks it a temporary deformity, due to a change of relations between the throat muscles and those of the larynx with a possible added factor of nerve disturbance. It is furthered by a backward development and irritable weakness of the central breathing mechanism. There is in it a factor of developmental neurosis. On the basis of this theory, a general tonic treatment is all that is required.

16. **Perichondritis of the Larynx.**—The rarity of this condition in this country is noted by Mayer, especially as compared with continental Europe. He explains its pathology as first congestion, then inflammatory edema ending in ulceration and breaking down. Other views have been expressed, however, and the question as to whether the changes are specific is denied by the author. He discusses the authorities as to the germs present, and reports a case in conclusion, reviewing other cases of laryngeal stenosis that may be compared with his. He thinks that his own case is of interest on account of the early development of laryngeal symptoms, the enormous submucous infiltration both before and after tracheotomy, the success that followed dilatation, making intubation easy under anesthetics, and the consequent easy deglutition with the tube in place. He thinks that this is the first case thus successfully treated.

18. **Hybrid Malaria.**—Porteous describes a form of this disorder which has occurred in many cases in his region, in Yonkers, N. Y., which, for want of a better name, he designates as above. It may be defined as a remittent fever with or without rose spots, appearing at times solitary and at other times in groups, both on the abdomen and sides. The invasion is not so insidious as in typhoid nor so sudden as in malaria. There is no distinct chill, but a chilly sensation is felt. The bowels are usually constipated, abdomen slightly tympanitic, urine often high-colored and offensive, some drowsiness, relieved by exercise and purgation. In the second stage there is a rise of temperature to about 99½ in the morning and 100½ in the evening, with pain in back and limbs, gradually increasing. The temperature later rises to 102 in the morning and 104, and even more, in the evening; insomnia. Rose-colored spots generally appear about the fourth day. At times there is considerable tympanitis. Sometimes there is a muttering delirium resembling that of delirium tremens. The Widal test is negative in all cases. The duration is one to four weeks. The failure of the Widal test was against the diagnosis of typhoid, as was also the rapid onset, the absence of iliac pain or gurgling, the eruption coming early and disappearing gradually, and the sudden subsidence of the fever, and rapid recovery. Malaria can be distinguished from it by the absence of intermittent febrile conditions, by the rash and the absence of a regular chill. The most successful treatment of this hybrid malaria is large doses of Warburg's tincture. If the diarrhea is obstinate acetozone seems to overcome it.

19. **Authority and Facts.**—Clemens takes exceptions to three statements, which he says have acquired a certain authority: 1. That early albuminuria in cases of sore throat is suggestive of diphtheria as against scarlet fever; 2, that of the absolute constipation in acute intestinal obstruction; and 3, the alleged lowering of arterial tension by drugs in chronic renal headache cases. These assertions tend, he says, to a routine practice, which is distinctly dangerous.

26 *The Fever of Dentition. Eugene R. Corson.
27 An Experience with the X-Ray in Kraurosis Vulvæ G. H. Stover.

20. **Extensive Operation on the Neck.**—The title of McPhatter's article explains its contents, but he reports the case in detail together with the discussion of the anatomic conditions, and gives illustrations. The results were waited for with some anxiety on account of the extensive interference with the cerebral circulation, but, contrary to the fears, there were no bad effects whatever. The pulse, temperature and respiration were practically normal, and the wound healed by first intention. In a few days the patient was out of bed, and in two weeks was able to return home. She has since been in good health. The illustrations show the success of the operation.

21. **The Irritability of the Facial Muscles.**—Dana reviews the normal and pathologic facial reactions to irritants, and finds that the face has normally only one true reflex, the supraorbital described by McCarthy and confirmed by Sailer. There is another apparent reflex that is really only a part of this, and there is still another one found occasionally in children, namely, the nasomental. This latter has also been found in abnormal conditions, as Graves' disease, melancholia, paresis, cerebrospinal lues, progressive muscular atrophy, and paralysis agitans. There are a number of other abnormal reflexes that are enumerated, but he sums up what he has sought to show as follows:

1. A list of normal facial responses.
2. A list of responses found in pathological conditions.
3. A demonstration that most of these responses are direct or indirect muscular reactions, not myotatic, and not reflex.
4. That the only normal reflexes of the face are the supraorbital and frontoorbital.
5. The description of a new reflex rarely found in normal faces, the nasomental.
6. The occasional presence of a frontal skin reflex.
7. Some clinical observations as to the significance of the abnormal responses.

22. **The Correction of Hip-Joint Deformity.**—In cases of deformity of the hip following diseases, the forcible methods of restoration that have been advocated are discussed by Gibney, and he reports a case where bad results followed. When sinuses lead to the joint, no matter of how long standing, it is unsafe to use forcible correction. He rather favors the use of subcutaneous methods, though they have been condemned by many surgeons.

23. **Retrodisplacements of the Uterus.**—Baldy discusses the subject of retrouterine displacements, which, he holds, are secondary as a rule to other conditions, ovarian trouble, adhesions, etc. He thinks that in a little while many of the operations now in vogue, such as Alexander's operation, hysterorrhaphy and ventrosuspension, will be obsolete and intra-abdominal operations on the round ligaments will take their place.

24. **Edema of the Glottis.**—Gittings and Jopson report a case and discuss the literature. They give the following conclusions as a résumé of the data discussed, with a pretty full bibliography:

1. Simple edema of the larynx usually occurs in cachectic diseases, especially of the heart and kidneys. In these there may be no apparent exciting cause, and the inflammatory symptoms are conspicuous by their absence.

2. Inflammatory edema of the larynx results from contiguity to other inflamed structures; as a local complication of the acute infections of erysipelas, variola, measles, scarlatina, influenza, etc.; or as a result of severe grades of inflammation in simple acute laryngitis. Bacteriological investigation will probably find that a streptococcus is the most frequent exciting cause.

3. Traumatism to the laryngeal structures may result in edema, depending on the degree of "insult" to the tissues or to a possible predisposition.

4. Among rare causes of edema of the larynx are angeioneurotic disorders and the blood dyscrasiæ, such as scurvy, purpura, etc.

5. The diagnosis rests on the evidence of palpation and, if possible, visual examination, as well as on the signs of laryngeal obstruction. Membranous laryngitis can not always be at once excluded.

6. Prognosis is unfavorable in all cases occurring in the course of chronic cachectic diseases and in severe types of the acute infectious diseases. In no case can it be other than guardedly favorable.

7. Treatment by intubation rarely affords relief unless the obstruction is infraglottic. Tracheotomy is absolutely demanded in extreme cases. The continuous inhalation of medicated steam is always to be employed; scarification and external depletion by leeches may be tried; cold and heat should be used externally and internally—cold as a prophylactic and heat as a stimulant and absorbent. General stimulating and supportive measures are necessary in all cases.

With the occurrence of edema of the larynx the time of election for the use of antistreptococcic serum has probably passed. As the infection is usually a mixed one, serum therapy does not

at the present time offer much prospect of relief, and its use must be empirical unless there is opportunity for bacteriological diagnosis from cover-glass preparations.

26. **Dentition.**—Corson criticises the recourse to the gum-lancet, holding that we should look elsewhere for the fever of dentition than in the mouth, and that it will be found, as a rule, in the digestive tract. Interference with the gums is, therefore, of secondary importance, if not absolutely harmful. A little use of calomel and castor oil is more often all that is required.

St. Louis Medical Review.

July 25.

28 *Pathologic Findings in a Case of Grip Peritonitis. Carl Fisch.

28. **Grip Peritonitis.**—Fisch reports the findings at the autopsy of a woman, aged 35, who died after an acute attack of grip, toward the close of which symptoms of peritonitis appeared. The conditions found were those of an acute purulent peritonitis, without any apparent point of origin, with an otherwise absolutely normal condition of the body, except a bronchitis, and the presence of a pure growth of Pfeiffer's bacilli in the inflammatory products and in the bronchi.

Cincinnati Lancet-Clinic.

July 25.

29 *Nitrous Oxid with Oxygen as an Anesthetic in Throat Work. II. Nitrous Oxid as a Preliminary to Ether Anesthetics. Samuel Iglauer.
30 Polypharmacy—The Evil of the Day. Charles P. King.
31 Surgery of the Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

29. **Nitrous Oxid.**—The following conclusions are deduced by Iglauer from his studies and observations as regards the use of nitrous oxid in nose and throat work:

1. Nitrous oxid with oxygen (or air) is by far the safest and most agreeable of all anesthetics.
2. The anesthesia is sufficient for a majority of cases.
3. When necessary the anesthetic can be repeated, either immediately or after an interval of several days.
4. For prolonged operations in the throat the nitrous oxid ether sequence is indicated (Bennet and Casselberry).

He thinks the drug has a much wider field of usefulness than to be used merely in dental practice. He also notices the combined use of nitrous oxid and ether, and its advantages in rapid anesthesia, and comparative safety and convenience.

32.—See abstract in THE JOURNAL, xl, p. 1524.

33.—Ibid., p. 1600.

34. **An Improved Filigree for Large Defects in the Abdominal Wall.**—Bartlett has devised a special form of wire filigree for strengthening extensive defects in the abdominal wall. He has observed that scars spread laterally, but not longitudinally to any great extent, and it seemed to him illogical to strengthen the scar with a great number of needless wires parallel to the axis of the incision, which could only stiffen the abdominal wall and prevent perfect mobility. His filigree, therefore, consists of a series of transverse extensions along a central axis or a row of long, narrow loops, extending each side. Experience teaches, he says, that it makes no difference whether the muscles and fascia be or be not completely drawn together as long as a suitable wire filigree extending sufficiently far out between healthy layers is promptly implanted and healed in. He gives the history of this method of using wire to strengthen the abdominal wall, and remarks that he has been able to observe his seven cases after operation for periods varying from two years down to eleven days, and has in no case had to remove the filigree or seen any disturbance that might be taken to indicate that such a contrivance might not rest indefinitely in its new bed. The logic of the operation is simple. No dependence is placed on preformed tissues. Faith is pinned on the new scar, which is prevented from stretching in extension by unyielding silver wires distributed through it in the proper directions. Of all the various forms of nettings that have been used, the simple one of flattened wire loops appeared to him as being the only one free from the evident disadvantages inherent to any sort of plate, as that is what a stiff filigree really is—one made up of wires which are of equal distance apart and running in both directions.

35. **Intestinal Perforation.**—The three successful cases out of the 13 operated on are reported by Harte. In one, perforation occurred during the middle of the disease, with the patient in good condition. It was immediately recognized and operation advised, but the patient's family's consent was not obtained immediately, necessitating a delay. The second was of the ambulatory character, coming on suddenly in a patient not much exhausted and presenting many of the characteristics of appendicitis with perforation. These are the most favorable cases for operation. The third case occurred when the vital energies were exhausted as the result of prolonged and exhausting disease, and shows that success can be obtained in some instances even then. The keynote in dealing with typhoid perforation is early recognition of the lesion, and to make an accurate diagnosis in the early stage, the medical assistant must be thoroughly conversant with the condition of the abdomen and be alert for the first symptom of muscular rigidity. Cases with hemorrhage are most perplexing, for they occur together. He thinks the ideal method would be for the surgeon to see all cases of typhoid fever day by day with the physician. Other signs are later in appearance and of less value. Shock is an important sign, but it takes time, and no time should be wasted. Immediate operation should be urged even in the presence of profound shock. He advises incision on the right side, starting with the cecum and appendix, examining the last three or four feet of the ileum, and as much of the colon as can be exposed. If no sign of peritoneal involvement is found, a mistake has been made in the diagnosis, and further operation should be discontinued. If signs of peritonitis are apparent and the cause not detected, a median incision should be made so that the entire length of the colon and the remaining small bowel can be carefully examined. Perforation can be easily hidden by lymph, therefore all portions of the bowel that are indurated or covered with lymph should be carefully examined. In 95 per cent. of cases a lateral incision will be most satisfactory. Of the 330 cases which he has analyzed, in 96 a median incision was made with a mortality of 78.12 per cent.; with the right lateral incision there were 123 cases, with a mortality of 68.37. In the other cases the site of the incision was not mentioned. The perforation should be closed with a silk suture in the direction that makes the least narrowing of the gut. No time should be wasted on attempts to cut or freshen the edge. The best stitch is the so-called mattress suture, as the running Lembert is likely to cut or tear out. Frequently the openings are multiple, and a careful examination should be made. Occasionally an opening may be too large for sewing up, and there are four procedures offered: 1. A plug of omentum may be fashioned and stitched against the perforation to form a patch; 2, resection of the bowel and an end-to-end anastomosis; 3, formation of an artificial anus, and 4, cutting off the damaged area or bowel from the general peritoneal cavity by carefully placing pieces of gauze between the folds of the bowel. Cleansing of the peritoneum and drainage are the most important procedures. The best results follow thorough flushings with salt solution, then with equal parts of salt solution and hydrogen peroxid, and finally with normal salt solution. This is best done by carrying a large tube down into the pelvis, and with vigorous flushing all foreign matter can be much more easily removed than by dry sponging. After the intestines are carefully replaced, a number of large gauze wicks are carried down to the bottom of the pelvis and the different parts of the abdomen between the coils to secure good free drainage. The abdominal wound should be left open, excepting when it is very large, when a couple of sutures at the upper angle can be introduced. It should have a liberal dressing of gauze over it, which is soon saturated, but should not be removed for three or four days, after which time it can be re-

moved by thoroughly saturating it with salt solution or hydrogen peroxid. The two important factors to be carefully considered in these cases are, he says, the early recognition of the lesion and dealing with it as rapidly as possible, and planning the operation so that not a moment is wasted, using the simplest technic, as every moment of delay will increase the mortality.

36. **Surgical Features of Typhoid in Children.**—See abstract in The Journal, xl, p. 1392.

37. **Dislocation of the Carpal Scaphoid.**—Ely reports a case of this rare injury, which he thinks may occur without recognition. In his case it was only recognized by the use of an anesthetic, when the muscles were completely relaxed. It may be sometimes responsible for some of the bad effects in so-called Colles' fracture.

Proceedings of the Philadelphia County Medical Society, Philadelphia.

June 30.

38 *Remarks on the Treatment of Paralysis Agitans (Parkinson's Disease). J. Madison Taylor.
39 *The Significance of Urinalysis in Pregnancy; with Special Reference to Eclampsia. Robert N. Willson.
40 A Case of Malignant Ovarian Cyst. Mordecai Price.
41 A Case of Dermoid Cyst. Ibid.

38. **Paralysis Agitans.**—The special feature of treatment recommended by Taylor in paralysis agitans is a series of carefully-directed movements, passive and active, by which contractures are overcome, the joints loosened up and flexibility compelled, and next, education in voluntary movements, almost solely of the extensors in the arms and flexors in the legs, not neglecting other muscles that are used. These must be instituted gradually on account of the sensitiveness of the tissues. As the practice is continued great soreness is manifest, much more than follows freeing of contractures of the cerebral and other forms of paralysis, on account of the breaking up of sclerosed tissues. The physician should himself outline the treatment and watch the progress, the most careful personal observation being needed. The movements are carried out, as all educated masseurs should know, while the patient is lying prone on the back and then on the face. The legs are raised and the knees pressed down to be held in full extension and finally rotated and pulled similarly to the treatment for sciatica. Much attention should be given the hands and feet. Weir Mitchell observed long ago that forced extension of the fingers and toes would overcome tremor for a few moments, though he has never used this fact therapeutically. After the limbs and extremities have been thoroughly treated and moved passively in the normal directions, the patient is seated on a level, preferably the floor, and the operator seizing the head, pushes it forward on the chest by gradual extensions and relaxations, increased day by day until the stiffened back muscles relax sufficiently to thrust the forehead almost to the knees. This causes much pain and subsequent temporary soreness. The trunk is rotated on itself until normal excursus is secured. Movements, passive and active, of the neck and upper torso and shoulders are of the greatest value, as here the scleroses are most manifest. The hardened tissues affect the adjacent and contained blood vessels and affect their caliber, impairing nutrition beyond. It has been Taylor's experience that in treating the neck stiffness of senility, when the structures become once loosened and elastic, the special sense organs, the eye and ear were notably improved, and the throat and voice showed improvement. The blood supply to the brain is increased with resulting mental improvement. He also emphasizes the value of dry cupping of the region of the erector spinæ muscles, thus affecting the spinal vasomotor centers governing the circulation in the cord. This procedure seems to improve the elasticity of the ligaments, etc. He also emphasizes the importance of giving careful attention to the structures about the loins and hips. To sum up, he says:

> The indications in Parkinson's disease are to overcome the growing apathy; to induce systematized return to normal activities; to use all gentle and yet forceful means to secure elasticity to the tissues, and finally to stimulate the circulation in the spinal cord by graduated pressure on the spinal areas through which reflexly many of the fibers in the cord can be restored to function and others improved. Above all, care and patience and persistence must be forthcoming on the part of the physician, and intelligent cooperation demanded in the patient. Whether a cure can ever be attained is only to be learned by increasing experience, but the profound improvement obtained in some exceedingly severe cases warrants the hope, and expectation, if moderate, can be at times exceeded. In so hopeless a condition these rational measures are certainly well worth a fair trial, and in the earlier stages of the disease they promise to secure abundant rewards.

39. **Urinalysis in Pregnancy.**—In answer to the question whether eclampsia can be foreseen and prevented, Willson offers the following as reasonable conclusions:

> 1. Careful urinalyses should be carried out in all cases of pregnancy at frequent intervals and with increased frequency as term is approached. 2. The most dependable indications of impaired renal function and of probable eclampsia, have been shown by general experience to be the presence of decided quantities of serum albumin, the diminution of the eliminated urea and the presence of a microscopic renal sediment (casts, renal epithelium, blood, etc.). The character of the latter, when accompanied by the well-known clinical signs of nephritis, always constitutes a working basis for an estimate of the probability of imminent danger. 3. Even if the urine appear perfectly normal the possibility of eclampsia must be considered, especially in young women. Eclampsia in such cases is of equal severity with that of cases in which the urine has given due warning of impaired renal functions. 4. When eclampsia supervenes on labor in a subject with previously (apparently) healthy kidneys, the tendency subsequently is toward a return to normal renal functions if the patient survives. This circumstance would seem to indicate still more strongly that the kidneys may actually have been normal up to the time of a temporary embarrassment and suspension of function. 5. Although we fail to find in urinalysis an unerring indication of the behavior of the case, it is a safeguard we can ill afford to neglect. Until the nature and pathogenesis of uremia and eclampsia are more thoroughly understood it would appear to be our best guide to safe treatment and accurate prognosis. 6. The prognosis seems to be vastly improved if eclampsia be combated by generous bleeding, followed by venous transfusion with normal salt solution. These measures reduce and dilute the poison in the circulation and relieve the cardiac distress. Free diaphoresis and purging are, of course, indicated.

New York State Journal of Medicine, New York.

49 The Roentgen Ray in Gynecology. Eden V. Delphey.
50 *A Study of the Indications for Nephropexy. Augustin H. Goelet.
51 *Septicemia and Death Following X-Ray Burns. Howard B. Besemer.

42. **Appendicitis.**—Ferguson would operate in all cases on patients who will submit within a few hours of the attack, but after that somewhat vague period has elapsed and the disease becomes localized, he would wait for the subsidence of symptoms and the formation of an abscess, treating the patient medicinally so as to avoid any spreading of septic matter into the abdominal cavity or interfering with the protective adhesion of the contiguous peritoneal surfaces. All the cases, however, should ultimately be subjected to operation.

44.—See abstract in The Journal of July 11, p. 125.

45.—Ibid.

46.—Ibid.

50.—Ibid., xxxix, p. 1204.

51. **Fatal X-Ray Burns.**—Besemer reports in detail a case of fatal septicemia following an *x*-ray burn. He says he finds three hypotheses for its cause: 1. Sepsis due to septic infection of the wound at operation, followed by absorption. He hopes this was not the case. 2. Did the chlorin sterilization practiced destroy enough epidermis or rather put enough tissues into condition of good culture medium for streptococci to multiply beyond all reason and overwhelm the system, or 3, was it the severe *x*-ray burning that furnished the culture medium? He has never seen chlorin do this before. If it was the cause, he was not able to show how the condition occurred. Inasmuch as the diagnosis of sepsis was only established at postmortem he is unable to guess when it began.

Oklahoma Medical News-Journal, Oklahoma City.

July.

52 The Mechanical Treatment of Hernia. J. R. Phelan.
53 *A Study of a Case of Dual Personality. S. Grover Burnett.

54 Impaired Digestion of Infants—Particularly Bottle-fed Babies. F. H. Monroe.

53. **Double Personality.**—The case reported by Burnett is an interesting one, evidently epileptic in its character. A peculiar feature of the case is that the subject was aware of his defect and managed to conduct business by taking careful notes in each state to which he could refer in the condition of amnesia that followed. He learned to think as two men, one taking up matters where the other left off, as recorded in his book. The case also has important medicolegal bearings, as he was decidedly dangerous in some conditions.

58 *Marasmus. Philip F. Barbour.
59 Pott's Disease of the Spine in Children. Its Complications. James H. Tebbetts.
60 Foreign Bodies in the Intestines. L. T. Royster.

55. **Fresh Air in Children's Diseases.**—Hastings remarks on the necessity of fresh air, the difficulty of obtaining it, and the methods adopted in the Boston Floating Hospital.

56. **Teeth Replacement.**—Earp reports a case where four lower incisors were knocked out by an accident, with laceration of the gums and only slight attachment of tissue on the anterior surface. The injured parts and the mouth were treated with an antiseptic solution mainly of boric acid, the teeth replaced, and after firm pressure for five minutes were kept in place by a pledget of cotton saturated with the same solution. Sedatives were given to produce quiet and a liquid diet instituted. After a few weeks the teeth were firm and later became uniform and normal and healthy. He thinks nature will show a tendency to assist when there is ample vitality as in childhood, and that the preservation of the teeth in this instance prevented depression, which, during the four to six succeeding years—the child being only sixteen months old—would have changed the expression of the features. The cutting edges not being in apposition would have made mastication imperfect and impaired digestion. The successful re-establishment probably prevented a destruction of the germs of the permanent teeth and avoided deformity and malposition.

58. **Marasmus.**—This condition is much more common among the dispensary class than in private practice. It may occur in well-to-do children that have undergone severe and prolonged illness. The pathology is not uniform. The cause is often very obscure, and though there is no difficulty in recognizing the atrophied child it seems to be due to vice of absorption, as Rotch says. Barbour, acting on this theory, has been trying copper arsenite in the treatment, in small doses, the more insoluble salt of arsenic being employed for the local stimulating action on the cells and mucous membrane of the stomach. Its effects, however, are not confined to the gastric membrane. It is carried into the bowel and that which is absorbed is carried to the liver, where it is again eliminated in the bile. This circular process seems to be stimulating to the atrophied intestinal mucosa, renewing its activity and bettering the absorption and assimilation. He has administered it three times a day after feeding in 3/100 of a grain doses dissolved in water acidulated with hydrochloric acid. While his experience has not been large with this method, it seems to indicate its use. He thinks the administration of cod-liver oil would probably be contraindicated. He has more good from its use externally than internally. The prognosis, he thinks, should be guarded in any case; the chances of tuberculosis are to be considered.

66 The Advantages of the Sims Posture in Cystoscopic Examinations. John A. Sampson.

62. **Hemo-Alkalimetry.**—The new instrument and method here described are dependent on spectroscopic examination of the blood and fading away of the absorption point of oxyhemoglobin with neutralization. The details are too elaborate for abstracting. Dare tabulates 75 cases of blood examinations, and the tables, he says, seem sufficiently interesting to merit a close study of the relation of alkalinity to physiologic and pathologic alterations of the blood. In enteric fever a marked decrease of alkalinity was the rule. In 23 cases where this diagnosis was made, the alkalinity was normal or below normal in 20. A decrease in alkalinity is also observed in tubercular disease with glandular involvement, while in tubercular meningitis or peritonitis the alkalinity shows an increase or falls late in the course of the affections. In gastric ulcer there is a fall in the alkalinity below the color index, while cancer shows an alkalinity above this. In malignant conditions generally the alkalinity was found to be normal or somewhat increased. The anemias showed a decided fall in alkalinity, while in chlorotic subjects the alkalinity followed closely the normal color index. In the latter disease attempts were made to increase the alkalinity by giving excessive amounts of sodium bicarbonate, but while the erythrocytes increased and the urine became alkaline, the hemoglobin failed to respond. In splenomedullary leukemia, the alkalinity suffers a marked decrease, while in splenic anemia and cholemia it shows an apparent rise. Catarrhal jaundice and amyloid liver both raise the alkalinity of the blood, and cholelithiasis showed an evident decrease. Croupous pneumonia, phthisis, influenza, rheumatic fever, rubeola, appendicitis, even in the presence of a frank leucocytosis, showed an increased alkalinity, while in malaria the results seemed contradictory. In chronic malaria it was subnormal, while in recent tertian malaria it was increased. The relation that the alkalinity bears to the excretion of urea needs investigation. These studies, imperfect as they are, he says, tend to show that in those diseases which present a marked decrease in the alkalinity, they at the same time show a marked increase in the quantity of urea eliminated as the amount of nitrogenous food is diminished.

64. **Pleurisy.**—Bunting has followed Widal and Ravaut's suggestion as regards the cytologic determination of the tuberculous nature of pleurisy. He studied a number of pleural exudates, particularly those from idiopathic pleurisy at the Johns Hopkins Hospital. He finds a decided fall in the number of polymorphonuclears in the second week, the exudate being almost entirely mononuclear, agreeing in this with Widal and Ravaut as regards idiopathic pleurisies and their tubercular character. He does not pretend to claim that all idiopathic pleurisies are tubercular, but they have an exudate remarkably uniform in cellular content and general characters which may be assumed to indicate a uniformity in the nature and etiology of the process. This uniform cellular formula, as others seem to have shown, is the formula of tuberculous pleurisy.

72 *Two Cases of Normal Pregnancy Following Operations for Extrauterine Pregnancy. Francis D. Donoghue.
73 *Some Curiosities of Cesarean Section. Ernest B. Young.

71. **Diphtheria.**—Rosenthal has not been able to reduce his mortality record to so low a percentage as to make him a believer in the "possible specific efficacy" of the serum. He suggests or intimates that there may be a decided difference in the quality of the serum, and that it is sometimes less effective in the same quantity as formerly, though he admits the reduction of mortality that has followed its use in the severer types. He now combines the serum with his old treatment. No case is so mild or treatment begun so early as to induce him to depend alone on antitoxin.

72. **Ectopic Pregnancy.**—Donoghue concludes that it would be well to carefully watch the post-operative course of ectopic pregnancy, as an increasing number of reported results show that normal pregnancy is many more times apt to occur than a repetition of an extrauterine. He thinks we would probably be doing right to conserve the pelvic organs, but careful watch should be kept for slight deviations from normal menstruation after operation. If the patient should elect not to be exposed to the danger of repeated extrauterine pregnancy, he asks will we not be obliged to concede that she may demand relief from any child-bearing?

73. **Cesarean Section.**—Young describes a number of curious cases taken from the literature of cesarean section performed in the crudest possible way, even by the patients themselves. Examples are given where goring by a cow was followed by the extraction of a dead or living child and the mother surviving, or both mother and child surviving. A case has been reported where a woman was cut in two by a cannon ball and a living child saved.

77 The Causes and Prognosis of Sudden Blindness. George W. Van Benschoten.

76. **Fracture of the Neck of the Femur.**—Peckham reports two cases of fracture of the neck of the femur, one treated by a bone peg, the fragment being placed in apparently perfect apposition and union restored in each case, though in each case there was a shortening of the leg. He accounts for this by the non-preservation of the proper lines or angle of the head to the shaft of the femur, and shows how this ought to be preserved by placing the wounded limb in an abduction splint. While this idea was original with him, it was also brought out by Dr. Royal Whitman, simply operating on the leg so as to restore the angle which the neck should form with the shaft. This can only be accomplished by markedly abducting the leg, therefore the leg should be placed in a strongly abducted position and fixed in plaster in this angle. He also calls attention to the Ridlon method of using the Thomas hip splint in case of this fracture in the aged.

82 Some Cases of Asthma Treated by Removal of the Middle Turbinate. T. W. Moore.

78. **The Principles of Rhinologic Practice.**—Pynchon offers the following conclusions from his review of the general principles of rhinologic work: "1. In the normal nose the nostrils should be of equal caliber and should jointly have a sufficient capacity to at all times supply the requirements of easy nasal respiration. 2. In the ideal nose the walls of the septum are practically plane, and are at no time or place touched by the tissues of the outer wall in either passage, and, furthermore, no points of contact exist elsewhere therein, so as to interfere with either ventilation or drainage, or prevent the normal evaporation of nasal moisture. 3. While in an ideal nose the septum is vertical and nearly plane, a moderate irregularity thereof will not impair the nasal respiratory functions, providing there are no points of contact or abrupt elevations therein, and the lumen at all points is sufficient. 4. Abnormal redness of the nasal mucous membrane is an unfailing sign of irritation, the cause of which is generally of a structural nature, and, therefore, amenable to surgical treatment. 5. The indications for operative interference depend on both the subjective and objective symptoms. A noticeable inadequacy of either nasal passage, the presence of excessive or retained secretions, or an abnormal redness of the mucous membrane at any point, are all evidences of abnormality, which, if coupled with inconvenience to the patient, invite corrective attention. 6. In the treatment of chronic hypertrophic nasal troubles, the indication is to remove all obstructive, redundant or pathologic tissues, and at all times the chief indication is to cause the defective nose to conform as nearly as practical to the contour and character of the ideal standard."

79. **Ethmoiditis.**—Woakes discusses the pathology of ethmoiditis, which he attributes to progressive fibrosis, and compares it to the conditions that occur in the kidney and possibly in the sclerosis of the nervous system and elsewhere.

80. **The Eustachian Bougie.**—Goldstein describes a method of using the eustachian bougie, which he considers a very valuable therapeutic measure in cases of obstruction or narrowing of the canal. It is often efficient when pneumomassage, catheterization and flation of the tympanic cavity have failed to produce good results. Its effect, he thinks, is mainly mechanical. As regards the electrical bougie he believes the addition of a mild galvanic current with its simple stimulating effect on the mucous membrane, nerves and muscles of the eustachian tube, enhances the value of the bougie, but as to its mechanical and electrolytic effects he expresses doubt. He thinks they may aggravate conditions. With the slightest cauterization or erosion of the surface, further narrowing of the tube of the lumen can not be prevented.

81. **The Electrolytic Bougie.**—Duel is an advocate of the electrolytic bougie. He gives the experience of a large number with whom he has corresponded in regard to it. The cases where he has found it of greatest value have been those in which he has used it only a few times at considerable intervals. Others' experience agrees with him. Even one passage has been sufficient. A small bougie, small current strength, considerable time and a great deal of patience are the best precepts to follow.

7 A Case of Acromegaly. Simeon Snell.
8 A Note on the Treatment of Chorea by Ergot of Rye. Eustace Smith.

1. **Erythemata as Indicators of Disease.**—Galloway divides these affections into a group of simple erythemata, the result of hyperemia, transient in character, as a rule, and producing no permanent changes, and one of the exudative erythemata, resulting from hyperemia, transudation and exudation as well as actual inflammation, causing changes that may be of some duration, or even permanent. The simple erythemata are results of action of the nerve centers, the dilatation of the skin arterioles, and in certain cases they may be of serious import as indicating constitutional conditions. It is very common to find that persons liable to these suffer from lack of resistance to infections, and irregular circulation. He reports a case showing that such a condition may develop into nodular and necrosing lesions in certain cases and be of the most serious prognostic significance. These conditions may also develop into the exudative erythemata, of which latter type he refers to certain parasitic disorders, as the erythemas of malaria due to the presence of hemameba in the blood, and trypanosomiasis. Probably the most common causes of exudative erythemata, which give rise to exudative lesions of the type of erythema multiforme, are the toxins produced in the digestive tract as a result of improper food, etc. A few cases have been recorded of erythema multiforme in connection with renal disease. In conclusion he remarks in regard to lupus erythematosus. He considers it a toxemia arising from various sources, and not essentially a tubercular affection.

2. **Hay Fever Antitoxin.**—Semon has utilized Dunbar's hay fever antitoxin in eight cases, several of which he here reports. His impressions from these are that it is a palliative rather than a directly curative measure. It is not to be expected that any single application will permanently ward off the disease, but it has given relief to some and has acted beneficially in postponing the attack in others. According to the spontaneous statement of at least two of his patients, it has rendered the actual hay fever attack much more tolerable than on former occasions. The main applicability of the serum lies in the direction of its postponing the occurrence of the regular attack. If further experience will show that prolonged and frequent application does not produce tolerance diminishing its efficiency or unpleasant by-effects, it will have added much to our therapeutics resources in this disease. After more extensive experience he may have to further modify his opinions.

3. **The Desirability of Operating Generally in Chronic Pancreatitis** is questioned by White, who reports a case showing that operation may not be necessary. He also questions the general fatality of the disorder, analyzing the statistics of Guy's Hospital in evidence of this. He thinks it is very rarely a fatal disease, probably not being responsible for more than one or two out of nineteen thousand deaths, and certainly not responsible for more than four.

4. **Cancer.**—The importance and value of the study of cancer in the lower animals, Bashford thinks, would enable us to orientate ourselves to an extent in the investigation, not possible by any other means. He thinks that the present pessimistic views of the hopelessness of investigating cancer are not justified in the face of what still remains to be done.

5. **Glandular Tubercles.**—MacFadyen and MacConkey have studied the postmortems of children to ascertain the presence of tubercle bacilli in the mesenteric glands. Only a few of the twenty-eight cases examined—eight altogether— were diagnosed as tuberculous. The remaining twenty were considered non-tuberculous; the examination, however, showed virulent tubercle bacilli, indicating, therefore, that this is much more frequent than ordinary examinations would lead one to suppose. One point of interest was the finding of tubercle bacilli in the mesenteric glands of a still-born child. They were also able to obtain material from the examination of 44 cases of adenoids and 34 cases of tonsils. The results, however, were entirely negative. They conclude that the tubercle bacilli are not usually found in these organs.

17 Note on a Case of Spurious Hydrophobia (Lyssophobia). W. S. Harrison.

10. **Gastric Ulcer and Its Surgery.**—Our knowledge of the etiology of gastric ulcer is still defective. Carless reviews the conditions in which the surgeon is most likely to be interested, those especially warranting surgical interference. One of these is recurrence or persistence without obvious complications as sufficient warrant for surgical interference, because it means chronic invalidism and may develop malignant disease; hemorrhage may also require operative treatment, especially when persistent or recurrent or threatening life. Perforation is one of the most formidable complications, and while the statistics vary, certainly is the cause of death in a considerable proportion of cases, 28 per cent. according to Fenwick and also Browicz, though Leube found it only 2 per cent., and the Massachusetts Hospital statistics give it only a little more, 3.2 per cent. The actual perforation is due to traumatism in many cases, though the injury may be very slight. Carless goes into details as to the operative treatment. A fourth complication demanding surgical treatment is one to which the stomach, like every part of the digestive tract, is liable and may occur whenever a chronic ulcerative lesion exists, viz.: localized abscess and, by extension of the infection, even a basal empyema may be produced. Finally complications necessitating surgical treatment arise as a result of the contraction which is always associated with the cicatrization of ulcers. Here the most marked trouble arises from the narrowing of the pylorus, but it may occur elsewhere and cause serious modifications of the shape of the stomach, such as the hour-glass stomach, etc. Sometimes the stomach may be divided into two equal pouches, and it may be possible to unite them by means of a Murphy button or a total excision of the stricture may be feasible. If gastroenterostomy is resorted to, it will have to be double to drain the two parts. When pyloric obstruction exists, the treatment may be either by pyloroplasty, pylorectomy or gastroenterostomy. Pyloroplasty is a simple procedure and should be successful. Immediate results are often excellent. The death rate, however, is about 10 per cent., and it can only be undertaken in the absence of adhesions. It is difficult also to open out and to suture up a very thick and indurated pylorus, and if the stomach is much dilated, and sags down, the contents are likely to stagnate in the pouch and no improvement follow. Where motor power is diminished it is of no use; and it must not be forgotten that duodenal ulcers may co-exist and produce stricture further down. Pylorectomy is sometimes useful, as is also gastroplication, but where all these procedures are contraindicated, gastroenterostomy must be relied on, and the results will probably be beneficial.

13. **Nauheim Treatment.**—The cases cured or greatly benefited by the Nauheim treatment, are, according to Thorne, those of dilated, enfeebled, irritable heart, a sequel of influenza, also cases of cardiac enfeeblement from excessive smoking and prolonged illnesses, such as typhoid, etc. Those that can be greatly benefited but not cured, include cases of rheumatic and of gouty origin where the valves have been permanently injured and there are signs of commencing cardiac failure. Among doubtful cases should be classed a large number of the more advanced forms of valvular affections in which the recuperative powers have been undermined by climatic effects, intemperance, or illness, and the patient is losing ground. The treatment may be tried in some of these cases when others have proved ineffectual, but it should be applied by one who is thoroughly conversant with it, and who can watch the smallest details, as a very slight variation in the bath temperature or the duration of the bath may have the most serious effects. The unsuitable cases are, according to Thorne, those who have been and are heavy drinkers, those who suffer from syphilitic heart affections, those with marked degeneration of the vessel walls, and those exhibiting symptoms of aortic regurgitation, and also very old people. In conclusion he says that a fortnight's or three weeks' change of air after the baths materially increases the benefit obtained, but the selection of place depends on the individual and his personal idiosyncrasies. Cases are reported.

15. **Croupous Pneumonia in Infancy.**—After the study of the statistics of the East London Hospital, and his personal observations, Riviere sums up the results as follows:

1. Croupous pneumonia occurs in infants below the age of two years as frequently as, and probably more frequently than, in older children.
2. In infants a diagnosis between croupous pneumonia and bronchopneumonia is often impossible, many cases of bronchopneumonia with lobar consolidation appearing in the postmortem room with a diagnosis of croupous pneumonia.
3. On account of this difficulty statistics based on diagnosis alone are quite untrustworthy.
4. This error can be largely eliminated after the manner described above. [An analysis of statistics giving about 25 per cent. of all cases under 2 years and nearly all above that age as croupous pneumonia.—Ed.]
5. The mortality in croupous pneumonia is largest in the first year of life (25 per cent.), is considerable below the age of two years (15.4 per cent.), but for children above this age is comparatively small (2.3 per cent.).

18. **Quinin in Prophylaxis of Malaria.**—Michon's practice, with which he has been very successful in Corsica, is to administer quinin hydrochlorate in the dose of 70 to 80 centigrams of quinin hydrochlorate every third day. Laveran in discussing his communication mentioned that the Italian tests of protection against mosquitoes with wire screening have resulted in reducing the proportion of persons affected with malaria from 40, 60, or 96 per cent. in the controls, to 1.9 per cent. of primary infection in 4,363 persons completely protected; 3.3 per cent. in 5,165 more or less protected, and to 10.9 per cent. in 802 persons only partially protected. Michon prefers quinin prophylaxis to "putting people in cages."

21. **Association of Appendicitis and Cholecystitis.**—Dieulafoy confirms by 2 cases personally observed Becker's recent statistics of 30 in which appendicitis coincided with a suppurative cholecystitis with or without peritonitis. He is convinced that the appendix is secondarily involved and its inflammation due to descending infection and therefore insists upon the importance of inquiring for gallstone antecedents and examining the gall bladder in every operation on the appendix. He cites in detail as an extreme case the one published by Grant in The Journal of April 18.

25. **Gelatin Solutions for Subcutaneous Injection.**—The committee charged with the task of reporting on the measures to be adopted to prevent accidents from this source, personally prefer that the solutions should be officially standardized, but as this is not practicable under the present regulations, they recommend that the solution should be 1 to 2 per cent. of gelatin in a 7 per cent. solution of sodium chlorid. It should be sterilized in quantities not over 150 c.c. in the autoclave with steam at a pressure of 115 degrees and for thirty minutes. They affirm that these precautions, strictly observed, will render tetanigenic infection impossible.

27. **Treatment of Arterial Hypertension.**—Huchard reiterates that the study of the arterial tension is the key to the pathology of many affections. The clinic has demonstrated that the peripheral heart sometimes takes the lead in morbid processes which commence in the arteries and finally involve

the left heart, with ischemia in the organs entailing numerous toxic accidents due to the early insufficiency of the liver and kidney. Arteriosclerosis, he states, is preceded for weeks to years by vascular hypertension due to various causes; the "maladie de fonction" precedes the "maladie de l'organe." It may be diagnosed by the sphygmomanometer, the stability of the pulse and its inverse type, and the diastolic reverberation of the aorta at the base of the heart and to the right of the sternum. When this latter reverberation is "clangorous" it indicates chronic aortitis and dilatation of the aorta, but when it is near the pulmonary artery, to the left of the sternum, it signifies hypertension in the lesser circulation. By "stability of the pulse" he means the lack of the usual difference between the pulse when the subject changes from the reclining to the erect position, or that the pulse is slower when standing. This inverse pulse is a sign of arterial hypertension. In treatment of this stage of presclerosis, the diet is of great importance, as the abuse of meat tends to pour into the blood more and more vaso-constricting poisons. Hearty eaters are more inclined to arteriosclerosis, he thinks, than hard drinkers. Meats should be abandoned for vegetables and milk, and diuresis promoted, the peripheral circulation favored by massage and muscular exercises, and by thermal baths. He warns against carbonated baths as directly enhancing the arterial hypertension, and relates 3 cases in which patients of this category had found their condition aggravated by a course of carbonated baths at Nauheim and returned to Paris to die. Presclerosis and all arterial cardiopathies characterized by hypertension of the blood formally contraindicate carbonated baths. A sharp distinction should be made between the "valvular hypotensive cardiopathies," he remarks, and the "arterial hypertensive," even when the latter exhibit a souffle at the orifice which is liable to cause them to be mistaken for the former. Blondel's new lacto-serum promises to be a valuable aid in combating arterial hypertension. [Robin has noticed that with the tonometer it was possible to determine a marked drop in the capillary tension after subcutaneous injection of even 1 to 5 c.c. of the lacto-serum. This is a serum obtained from animals previously injected with small repeated doses of milk.—ED.] Organ therapy may be useful in certain cases, especially in the arterial hypertension sometimes noted in the menopause and which frequently terminates in arteriosclerosis. Ovarian therapy in these circumstances is better than drugs. He considers veratrum viride unreliable or dubious, and rejects also the iodids, theocin and theophyllin, theobromin and ethyl nitrite. He prefers trinitrin (nitrate or trinitrate of glycerin, nitro-glycerin) in progressive doses, two or three drops at a time, three to six or eight times a day until a bearable headache is induced. Tetranitrol (erythrol tetranitrate) in tablets of 1, 2 or 5 mgm. or 1 cg. several times a day until a mild headache is likewise induced. At this moment the dose should be slightly reduced. The vaso-dilating action is nil until the slight headache stage is reached. Given with these precautions there is no fear of toxic accidents, and they can be continued for weeks and months, on condition of suspending them for eight to ten days during the month.

28. **Fibromyoma of Vagina.**—Potel has observed 2 cases and collected 160 that have been published. They demonstrate that a fibrous tumor in the vagina, if left to itself, almost inevitably proceeds to ulceration and necrosis with possible serious infection. Death in the fatal cases was due to infection from this cause or hemorrhage.

29. **Twin Pregnancy Combined Intra- and Extra-Uterine.**—Bichat became interested in this subject from a case of this kind personally observed, and found 49 similar ones in the literature. In only one of the entire number did the mother and both children survive. In 2 others both children survived, but the mother succumbed. In 7 instances, after delivery from a supposed simple pregnancy, a tumor in which movements and a pulse could be observed was discovered in the abdomen, but no attempt was made to open it and the movements and pulse ceased in the course of a few hours to ten days. In the total of 50 cases, 12 came to term; in only 17 was the uterine fetus delivered alive; and the "ectoper" in only 3, as mentioned above. The mother survived in 27, but in the 20 cases of later date than 1880 there were 14 recoveries. The death of the mother was generally due to rupture of the ectopic pregnancy; in 12 the hemorrhage was fulminating before intervention could be attempted; in 7 the mothers succumbed notwithstanding operative treatment—in 4 from hemorrhage and in 3 from septicemia. He reviews the various cases in detail and concludes that treatment should be the same as for a simple ectopic pregnancy, that is, immediate intervention unless near the term. The danger of uterine abortion should not deter from prompt operation. But when first diagnosed near to term, and there are no alarming symptoms, it may be postponed under the closest supervision, with the hope of preserving alive the mother and both fetuses. The mortality for operative treatment has been 30.44 per cent. in 23 cases, while with expectant treatment it was 62.5 per cent. in 24 cases.

31. **Perigastritis with Adhesions.**—Vautrin's experience and that of others in the 29 cases he has found recorded, indicates that small, partial adhesions accompanying an insignificant gastric lesion may be detached with complete and definite cure. In case they are more numerous and compact, it may be wise to terminate by peritonization of the raw surfaces and resection of the gastric ulcer if one exists. But when the perigastritis has surrounded the stomach with a mass of adhesions and part of the stomach itself is much altered or the pylorus is compressed, or the parts have grown together, gastroenterostomy should be preferred. Whatever method of treatment is followed, the post-operative cure may not be immediate. All surgeons agree in this. After removal of the adhesions some time may elapse before the functions of the stomach are restored to normal. The vomiting may continue for several weeks, but gradually the symptoms subside to complete disappearance in time. The diet should be regulated to restore the chemistry of the stomach to normal.

33-34. **Indications for Hysterectomy in Acute Puerperal Infection.**—Pinard has performed this operation in 2 cases which were apparently favorable for it, but both patients succumbed. In one an unsuspected streptococcus left pleurisy was discovered and in the other, suppurative phlebitis of the right utero-ovarian veins. He affirms that neither the clinic, bacteriology nor pathologic anatomy are as yet able to afford any reliable indications for hysterectomy in acute puerperal infection.

Cortiguera has found 141 cases on record in which the uterus was removed for this cause. In 68 the patients recovered, in 73 they died. He believes that vigilant prophylaxis will

prevent puerperal infection and that vigorous intrauterine treatment at the proper moment will cure almost every case, but in the few exceptional cases in which these measures prove inadequate, hysterectomy may be done. The cases suggesting this treatment are those in which the infection is localized in the uterus, adnexa or pelvic peritoneum, but peritonitis or generalized infection are not absolute contraindications. Before operating it must be determined that the infection does not originate in the perineum or vagina, that it is not hematogenic with the uterus merely a subsidiary factor, and that the defensive glands, liver and kidney, are intact. Collapse or extreme weakness likewise contraindicate hysterectomy in such cases.

37-39. **Conservative Surgery of the Adnexa.**—Treub's address has been already abstracted. See ¶52, p. 133.

Fargas remarked in the course of his address that preservation of the tubes, without the ovaries, does not respond to any known indications.

Gutierrez regards as incurable the cases of chronic peritoneal and cellular inflammation with sclerosis and a purulent, inaccessible focus or one discharging into the upper portion of the rectum. In cases of recent inflammatory exudate without sclerosis or suppuration, good results may be obtained by promoting absorption, especially by Pincus' method of compression by the weight of a colpeurynter bag filled with mercury or lead, the patient slanting. (Pincus' colpeurynter for this purpose was described in THE JOURNAL of Oct. 4, 1902, p. 868, ¶57.) Thermal baths are also useful. When the exudate displays a tendency to sclerosis and causes constriction of the rectum, with or without a fistula, with serious gastrointestinal disturbances, the subcutaneous or submucous injection of thiosinamin according to Juliuberg's directions for treatment of cheloids and scleroderma, may be advisable.

48. **Epidural Injections in Urology.**—Cathelin's technic has been described recently in these columns, p. 286, ¶38. He now announces that he has cured with it 75 per cent. of all his cases of incontinence and has successfully applied it in all kinds of neuropathies affecting the urinary apparatus, such as night pollutions, impotence, psychopathic pollakiuria, false urethritis, false prostatitis and false cystitis—the "false urinary subjects." The dynamogenic effect has been established beyond question, confirming Cathelin's early assumption in regard to spinal inhibition by nervous traumatisms and shock affecting the roots and spinal cord centers in what he calls the "cone."

52. **Exaggeration of Tendon Reflexes in Autointoxication.**—In 12 subjects examined in Grasset's service the exaggeration of the tendon reflexes accompanied unmistakable signs of general intoxication. The number included 2 cases of pregnancy autointoxication, 2 of chlorosis, 3 of Bright's disease, 1 of chronic sclerous nephritis, 1 of subacute nephritis, 1 of biliary lithiasis, one of Laennec's cirrhosis and 1 of typhoid fever. The "antitoxic insufficiency" was evidenced by various symptoms on the part of the nervous system, or of the digestion (vomiting, diarrhea), circulation (hypertension), respiration (dyspnea), kidneys (pollakiuria, albuminuria, edema) or liver (icterus, pruritus). The tendon reflexes were exaggerated in all, sometimes in every limb, sometimes only in the arms. In some this exaggeration of the reflexes paralleled the intoxication in its rise and fall. Grasset attributes it to the contact of the toxic blood with the nerve centers—an exaggeration of the excito-motor power of the nerve centers of autotoxic origin.

58. **Fasciculus of Turck.**—Marie presents numerous arguments, with 21 cuts, to sustain his view that the fasciculus of Türck is what he calls a temporo-protuberantial fasciculus. The most important contingent of fibers is derived from the third temporal convolution. Although he considers that we now have quite correct notions as to its anatomy, its physiology is still a blank.

63. **Etiology and Biology of Tumors.**—In this address at the Madrid Congress Israel discussed the parasitism of tumors and the increase of cell proliferation in tumor formation. He combats the parasitic theory and explains the destructiveness of sarcoma by the great proliferating power of the cells, while in carcinoma the loss of the vitality of the base is the principal factor in the malignant spreading of the neoplasm.

65. **Mesothelioma Malignum Carcinomatoides.**—This is the term coined by Woolley to describe tumors of mesothelial origin. He reports a case, a primary carcinoma of the suprarenals, in a man of 43, accompanied by metastases in right lung, brain and retroperitoneal glands. He adds a review of 21 cases of cancer of the suprarenals of which he has learned.

66. **Spinal Angioma.**—The first symptoms had been noted about two years before death, pains and coldness of the extremities, progressing to paralysis of the legs by the end of the year. The autopsy revealed an angioma at the sixth dorsal vertebra, extending into the spinal canal and below the costal pleura.

70. **Lymphosarcoma on Pleura Extending Into Spinal Canal.**—The tumor was observed on a young woman, and is the third case of the kind on record in which a tumor in the mediastinum had invaded the spinal canal.

75. **Shriveling of Suprarenals in Addison's Disease.**—Besides the 2 cases described by Simmonds, there have been 24 published. Simmonds is inclined to regard this bilateral contraction of the suprarenals as an idiopathic atrophy or the result

of some inflammatory process. He queries whether syphilis may not be incriminated in the etiology.

82. Treatment of Intestinal Catarrh.—Boas criticises von Aldor's communication on this subject, the principal points of which were given in THE JOURNAL of June 27, p. 1791. He thinks that the long tube may simply roll up in the rectum instead of entering the large intestine its entire length, also that injection of as much as three quarts of water may be a dangerous procedure in such conditions. He also wonders why the measure is equally effective in the opposite conditions of constipation and diarrhea, stimulating peristalsis in one case and inhibiting it in the other. He thinks the unmistakable benefit derived must be due to the high temperature of the injections, and this principle has been proclaimed for years by others. Boas places supreme reliance on dietetic measures as a means of curing chronic catarrh of the large intestine, but the "obstipation diet" must be kept up for months to years or recurrence is liable. Aldor, on the other hand, releases his patients from dietary restrictions as he mentions in a reply to Boas in a later number. The latter has established that fluid injected into the rectum with a short tube, the subject reclining, soon finds its way into the cecum and emerges if there is a fistula at this point, consequently a long tube is not needed to flush the bowel.

86. Research with Radium Rays.—London used for all his tests 30 mg. of radium bromid in a rubber and metal box with a mica cover. He found that radium rays are able to kill mice without direct contact. Twenty-one grown mice and 6 controls were placed in glass vessels, 3 or 4 in each, and the box of radium was laid on the cover of the vessels for one to three days. The controls were lively at the end of the fifth day, but the other animals were all dead by this time. The symptoms noticeable about the third day indicated depression of the cerebral nervous system at first, followed by arrest of the functions of the cerebrospinal system in four to nine hours. The most profound anatomic alterations were in the skin and cerebral cortex. He further refers to the fact that if a stick of sealing wax is rubbed with flannel, scraps of tissue paper will cling to it, but he found that if the wax were passed over the radium box after being rubbed the tissue paper was not attracted to it. On the human skin the rays induced a so-called "cold gangrene" in tests on himself and his assistant. The lesions were so peculiar and characteristic that they must be designated as dermatitis radiogenes. He also states that arterial blood became dark colored under the influence of the rays. In his tests on blind subjects he found that they perceived a visual sensation when the radium was applied to their eyes, but this occurred only in those subjects who still retained a certain perception of light. The blind who had never experienced the sensation of light afforded negative or contradictory results. Blind subjects still able to distinguish between light and darkness were able to see in outline dark objects held against the fluorescent screen lighted by the radium rays. Two lads blind from atrophy of the optic nerve were thus able to learn by the silhouettes all the letters of the Russian alphabet and make out entire words. He also states that he found certain persons who were able to tell—by the visual sensation experienced—when the radium was brought close to the back of their heads, but only when approached to a certain point. He suggests that this may possibly be the result of excitation of the visual center at this point by the rays. The visual impression is perceived from the radium rays even when the eyes are closed, bandaged and covered with three or four superposed hands. His concluding statement is to the effect that it is possible to examine articles through the microscope in a dark room with merely the light from a good screen under the influence of the radium rays. His research was conducted at the Institute for Experimental Medicine at Berlin.

88. Treatment of Hypertrophied Prostate.—Casper reviews his experience with 131 patients with enlarged prostates. Four out of 61 cases not operated on were cured; 38 improved; 8 not benefited; 4 grew worse and 7 died. He emphasizes the importance of slow and gradual evacuation of extreme distension of an insufficient bladder. The fluctuation in tension is the most serious factor in the development of cystitis, he believes. Caution is pre-eminently needed in the absence of cystitis. He never resorts to catheterization in such cases unless there is as much as 300 to 400 c.c. of residual urine with a capacity of 500 c.c. He determines the capacity by injecting sterile water followed by 100 to 200 c.c. of silver solution. Of the 51 cases of considerable residual urine 2 were cured; 34 materially improved; 8 not benefited; 4 grew worse and 3 died. The cases of what he calls "prostatismus" were more difficult to treat. He did not use the catheter but applied hot sitz baths, thermophore compresses, soothing or narcotic remedies. Only 2 out of 10 were cured in this category. The effects of prostatectomy through a sectio alta were very serious; 2 died, and although the 2 others recovered, their lives hung by a thread for a time. Threatening heart weakness was observed in all and he regards this operation as too severe for any but younger men with vigorous constitutions. He has had no experience with the perineal operation.

89. New Inhalation Method of Treating Tuberculosis.—Dr. R. Schneider when traveling in Australia was impressed by the benefit derived by the natives in pulmonary affections from the use of a decoction of eucalyptus leaves. A powder has been prepared on this basis and put on the market under the name of Sanosin. It contains the pulverized leaves and oil of the Australian *Eucalyptus citriodora maculata*, flowers of sulphur and charcoal. The powder is burned on an earthenware plate over a small alcohol lamp for twelve to twenty minutes in an ordinary sized room. Danelius has been experimenting with this remedy for six months in private and dispensary practice and has found that tuberculous subjects who remain for one to three hours or all night in a room impregnated with the fumes of the burned powder are very much benefited. The relief in respect to the cough, expectoration, night sweats and appetite is pronounced and has been permanent to date. The fumes do not affect well persons unfavorably and his experience has convinced him that for old chronic bronchial catarrh there is no other treatment able to afford

such services. None of his patients can be considered cured of their tuberculosis to date but all have been immeasurably relieved. The patients sleep so well afterward that one inquired whether the powder did not contain some narcotic.

90. **Lysol Poisoning.**—One of Liepelt's patients had taken 100 gm. an hour before reaching the physician, and another 50 gm. two hours before. Beside his 4 cases he has found 41 in the literature. Four died out of the 11 in which the poisoning was from external application, and 13 out of the 30 who had taken the lysol internally. Only 3 of the latter 13 fatal cases had been treated by rinsing out the stomach. All the patients who recovered had been treated by rinsing out the stomach and with this he saved also the 2 severe cases first mentioned. He used 22 to 25 quarts of water for the rinsing, continuing it until the escaping fluid no longer smelt of the drug, and supplementing it with large doses of camphor. Consciousness was not regained for four to twelve hours in these cases. In 10 of the fatal cases the lysol had been taken by mistake for some other medicine; in 3 with suicidal intent.

91. **Cancer on Cold-Blooded Animals.**—Pick remarks that malignant tumors, especially carcinomata, have been found on horses, hogs, sheep, cattle, dogs, cats, goats, rats and mice, but he believes that he is the first to publish in a medical journal cases of cancer on cold-blooded animals. He has found a cystoma testis with carcinomatous inclusions on a Japanese giant salamander (*Kryptobranchus japonicus*); a large medullary carcinoma involving the thyroid on the neck of a Brazilian turtle, and gives illustrations of adenomata found on salmon and trout by Miss Plehn and published in a fishery journal. The analogy between the histologic structure of these neoplasms on these cold-blooded creatures and those on man is striking. The localization also corresponds to that on man. He adds cuts of some ulcerative pseudo-tumors found in the stomach of a dog in which specimens of *Spiroptera sanguinolanta* were ensconced. Grassi has found that this round worm completes its life cycle in the cockroach. The latter eats the embryos in dogs' dejecta, and the dog then eats the cockroach. Pick thinks that the ulcerative processes in this case suggest a more intimate connection between intestinal parasites and the mucosa than has been heretofore recognized. His researches to discover malignant neoplasms on birds and fowls have hitherto been fruitless, and he is inclined to believe that the cases reported have been erroneously diagnosed and were in fact tuberculous processes.

94. **New Method of Preparing Albuminous Foods.**—This article refers to a process which allows the complete separation of starch from the albuminous substances. The latter can thus be used separately as a by-product and afford an inexpensive and easily digested food which is being put on the market in the form of flour, macaroni, etc., absolutely free from starch by the most searching tests.

95. **Suggestion for Improved Construction of Hospital Wards.**—Aufrecht has had the sanatorium at Loslau constructed according to his designs and regards the result as a distinct advance. His aim was to secure private rooms for the patients, perfect ventilation and the minimum of expense. This he accomplished by having a large ward partitioned off into a corridor down the center opening into small rooms each side, the partitions reaching only two-thirds of the height of the room. Each of the small rooms has a bed and window, but the ventilation is usually from end to end of the corridor down the center. He has found it perfect. For hospitals he suggests the construction of wards on the same principle, only in the shape of a semicircle with a wide corridor for the base. The partitions should extend from the outer wall part way toward the center, like the spokes of a wheel, thus forming a semicircle of small compartments with a bed against the wall on each side and a window in the middle. The attendant, seated in the semicircular open space, could see every bed in the ward while each two patients would have the privacy of a separate room. In case one of the inmates of a compartment is dying, the other one could be moved out if desired. The ventilation from end to end of the long corridor at the base of the semicircle would be ample to keep the air pure while the patients would not be exposed to any draft. The open semicircular space would also prove a convenient gathering hall for the inmates able to be up.

97. **Protein Chromogen Reaction with Gastric Cancer.**—Glaessner announces that if a scrap of cancer tissue be placed in normal gastric juice the albuminoids are decomposed and the tryptophan (proteino-chromogen) reaction is constant. This does not occur with non-cancerous tissue.

98. **The Case of Laboratory Plague at Berlin.**—In the discussion at the local medical society of Dönitz's report on this subject, Dr. Plehn remarked that his extensive experience in plague countries warranted him in the assertion that the danger of contagion of bubonic plague is very slight. The Europeans in India scarcely ever contract the disease notwithstanding their almost complete lack of care. He thinks there need be no fear of the spread of the plague into an epidemic from isolated cases in Europe. He added that he had never witnessed any conclusive results from serum treatment or prophylaxis. In editorial comment the *Wochenschrift* urges that persons engaged in such laboratory work should be ordered to report daily that their health may be known, and they should always be regarded as "suspects."

110. **Influence of the Dwelling on Susceptibility to Tuberculosis.**—See editorial in JOURNAL, Aug. 1, p. 23.

112. **Study of the Blood After Splenectomy.**—The results of careful research in the case described fail to demonstrate any participation of the spleen in the formation of red corpuscles or that it shares to any extent in the production of most of the leucocytes, although it may coöperate in the production of lymphocytes. On the whole, extirpation of a healthy spleen does not seem to affect the blood production or suggest any participation of this organ in the process.

114. **Enlargement of Spleen in Infectious Diseases.**—Grober states that in acute sepsis in mice and in acute miliary tuberculosis in guinea-pigs the enlarged spleen was found to contain much more water than normally. All the inflamed tissues contained an abnormally large proportion of water. He therefore

attributes the enlargement of the spleen in infectious diseases to hyperemia of the organ.

116. **Atmospheric Pressure in Esophagus and Stomach.**—Schlippe states that during inspiration in ordinary conditions the pressure in the esophagus is negative while in the stomach it is positive. In both it is under the influence of the respiration. He found that the lumen of the cervical portion closes during inspiration, and that the cardia sometimes closes but not always.

121. **Functional Kidney Tests.**—Casper states that the phloridzin functional test of the kidney allows an exact diagnosis of the location of a kidney affection; it affords information in regard to the composition and functioning capacity of the other kidney not to be obtained in any other way, and makes it possible to avoid the preventable "kidney deaths," and thus materially diminish the mortality from kidney operations. Israel has been denying the reliability of the phloridzin test, and announces that without it he has been successful in all but 5 of his last series of 80 operations on the kidney. These assertions roused Casper to analyze Israel's cases published before this last series, and he unhesitatingly declares that many of the fatalities might have been prevented if the phloridzin test had been known at the time and applied. Out of the 9 "kidney deaths," 4 at least were directly due to the removal of the kidney when the remaining kidney was already fatally compromised. Even in his last series of 80, he had 5 deaths while none occurred in Casper's series of 72 cases operated on after he had determined the functions of the remaining kidney. His record to date is 88 cases operated on by various surgeons and the findings of the tests were confirmed by the operation in every instance. The kidney stated to be diseased by the test was found diseased, and the kidney proclaimed by the test to be sound was found sound, when intervention was undertaken contrary to the findings of the test. Nine of the 88 patients died and the findings confirmed the results of the test in the 7 autopsies that were allowed. None of them could by any possibility be called a "kidney death." In 3 other cases the test showed partial or complete absence of function in the second kidney, and the autopsy later showed contracted kidney in one, amyloid degeneration in one and in the third the absence of a second kidney.

123. **Affections of Lateral Columns and Spastic Paralysis.**—Rothmann comments that nothing hinders more the progress of science than clinging to certain theories when the facts observed no longer sustain them. Such a theory is the acceptance of spastic paralysis as a symptom of an affection of the crossed pyramidal fasciculus or of the posterior or lateral tracts in general. His observations on man and experiments on monkeys have convinced him of the contrary. The cases of true spastic paralysis are so rare that they can scarcely serve as a basis for a definite morbid entity, but if this is accepted, then the affection should be known as "Erb's spastic pseudoparalysis," and the conception of spastic paralysis should be reserved for the spastic, paretic symptom-complex observed in cases of actual paralysis of the legs. The exaggeration of the tendon reflexes and the slight weakness of the extremities are due to the degeneration of the pyramidal tracts. The spastic condition is the consequence of some irritating action on the cells of the anterior cornua, the cause of which has not yet been anatomically established and may be manifold. The degeneration of the pyramidal tracts can at most only afford a predisposition.

125. **Experimental Tests of Dissemination of Typhoid by Butter.**—The experiments reported by Bruck from the Institute for Infectious Diseases demonstrate conclusively that the transmission of typhoid fever may easily occur by means of butter. In some of the tests water in which a cloth slightly soiled with typhoid stool had been washed was used to rinse out the vessels in which the cream was kept. Butter made from the cream developed colonies the first day. The typhoid stool used for the purpose contained only about 16 colonies to a plate. Although not absolutely certain, Bruck believes that the bacilli are liable to be more numerous in the butter than in a corresponding amount of cream or buttermilk. Living bacilli were found in the butter as late as the twenty-seventh day. They seemed to increase in number during the first few days.

126. **Symbiosis of Influenza Bacillus.**—Neisser reports that he has succeeded in cultivating through twenty generations some influenza bacilli, derived from a case of measles conjunctivitis and found associated with xerosis bacilli. The influenza bacilli died out except when this symbiosis with the xerosis bacillus was maintained. He suggests that the latter may modify the medium in some way (blood agar) to render it more favorable for the influenza colonies. He found that the diptheria bacillus will also serve as "nurse," as he calls it, for the influenza germ in this way. but not so successfully as the xerosis bacillus. It is possible, he adds, that symbiosis with certain invisible bacilli may be an important factor in the flourishing of the influenza germ.

129. **Tuberculosis and Cancer in Same Family.**—Aronsohn adds 3 more to his previously published list of 11 families in which cancer and tuberculosis had both occurred, and reports another in which the daughter died from tuberculosis after a course at a sanatorium and the mother exhibited a cancer of the uterus soon after. The father and another child now show symptoms of tuberculosis and one other has hematemesis which suggests malignant disease. Croner's statistics taken from the records of the Victoria Life Insurance Company show tuberculosis in 13.9 per cent. of the families in which cancer has occurred, and tuberculosis in the parents in 22.7 per cent. of the policyholders that have died from cancer. Aronsohn cites these facts as testimony in favor of his assumption that cancer, lupus and tuberculosis all belong to the same family.

130. **The Plague Case at Berlin.**—Kirchner ascribes Dr. Sachs' infection to the following circumstances: The latter was always extremely careful in observing the precautions imposed in the Institute to prevent infection, but one day he aspirated with a Pravaz syringe some of the glandular juice from a bubo on a guinea-pig that exhibited a typical case of experimental plague. He then expelled the juice from the syringe on a plate of agar according to the usual technic, but for some reason the fluid did not issue as usual in a fine stream, but in the form of a spray. The authorities ascribe the infection to inhalation of some of the droplets of this spray, as the incubation from this date corresponded to the accepted period of plague incubation—five days. During the great epidemics of plague in history the physicians kept at a distance from the patients and indicated their orders by a long wand, as the profession afforded many victims until this precaution was observed. Laboratory experiments show that the plague ba-

cilli die in water in less than two days, and also in the cadaver very early. The danger lies in the patient himself, his linen, dejecta, etc., and the disinfection of the residence afterward is of much less moment than systematic and repeated disinfection at the bedside.

138. **Alcoholic Retrobulbar Neuritis in Antiquity.**—Deneffe cites one of Martial's epigrams (No. 78, Sixth Book) to show that the deleterious action of alcohol on the eyes was known at that date, 54 to 98 A. D. Phryx, a hard drinker, warned by his physician that he would lose the sight of his one eye if he continued to drink, exclaimed: "Farewell, eye," and continued his alcoholic excesses. "Phryx drank the wine and his eye the poison, with the result that he became totally blind."

142. **American Contributions to Development of Modern Therapeutics.**—Baruch quotes, among other interesting matter, Oliver Wendell Holmes' writing in 1843 in regard to the infectiousness of child-bed fever, and compares his statements with those of Semmelweis who proclaimed the same idea in Germany in 1847, independently of the American. Both met with ridicule and opposition from their contemporaries at first, but conviction soon followed, and energetic antiseptic measures were then adopted. Baruch himself was the first to denounce the latter which were being enthusiastically advocated by Gaillard Thomas at that time, 1884. Fordyce Barker supported him and at a symposium on the subject, summoned by the latter, Thomas receded from his position and this change of views banished strong antiseptic vaginal douches from obstetric practice.

144. **Early History of Two Physiologic Problems.**—The relations between the nervous system and nutrition, and the internal secretions of the organs, are the two problems referred to. Each was discussed in scientific gatherings as early as the seventeenth century, and Neuburger relates some of the curious ideas advanced on the subject and recorded in the transactions.

146. **Plague in Turkey.**—Stékoulis states that the plague has existed in Assyria but strictly localized, since 1826, but Turkey has been free except for a small epidemic in 1885 near Bagdad. In 1897 it appeared at Djeddah and since then occasional cases have occurred at various points, including Constantinople, but the number of cases has not surpassed 471 with 338 deaths. All but 101 occurred at Djeddah or Yambo. With the exception of the old localized endemic in Assyria, the plague cases never caused wide contagion, and although the disease clinically is the same as in the days of the "black plague," yet epidemiologically it has nothing in common with it. If it were not for its traditional name, he concludes, the populace would be less alarmed at the progress of the plague and sanitary measures might be modified in accordance with the teachings of modern science.

148. **Maritime and Colonial Medical School at Naples.**—Rho states that over four millions of Italians live outside of Italy. A million and a half are settled in Brazil and half of these pursue agricultural occupations. Emigration has been constantly increasing during the last thirty years, and now surpasses that from any other country. During the first half of 1902, 354,000 emigrants left Italy, 148,000 permanently. The majority, however, go from one country to another in search of work and frequently return to Italy, so that the temporary emigration is always larger than the permanent, and the population of the country still keeps on increasing. A law has been in force for about a year which regulates the emigration and guards the poorer emigrants both morally and physically. The emigrant ships are obliged to carry a naval medical officer as a government medical official, and if the emigrants number more than 700, a civilian physician accompanies him. The naval medical officers are trained in climatology and tropical pathology, naval hygiene and the pathology of the ports to which the ships are destined. Chairs of tropical pathology and naval hygiene have been founded at Naples and placed in charge of Rho and Pasquale, both upper medical officers in the royal navy. A special school for tropical diseases has also been founded, in charge of Giaxa and four other professors, and a hospital for returning emigrants. The school has already 37 young physicians as students who are fitting themselves for this maritime service, or its branches in the seaports.

149. **Linnaeus as a Physician.**—Ebstein refers to Hektoen's article on this subject in THE JOURNAL of Sept. 13, 1902, but has had access to other sources of information and supplies some further details. Two portraits of the great botanist accompany the article.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

INTERNATIONAL CLINICS. Ballantyne, M.D., Edinburgh, and John Harold, M.D., London; with Regular Correspondents in Montreal, London, Paris, Leipsic and Vienna. Volume II, Thirteenth Series. Cloth. Pp. 311. Price, $2.00. Philadelphia and London: J. B. Lippincott Company.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume VI, General Medicine. Edited by Frank Billings, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. Salisbury, M.D., Professor of Medicine, Chicago Clinical School. May, 1903. Volume VII, Pediatrics. Edited by Isaac A. Abt, M.D., Assistant Professor of Medicine (Pediatrics Department), Rush Medical College. Orthopedic Surgery. Edited by John Ridlon, A.M., M.D., Professor of Orthopedic Surgery, Northwestern University Medical School. June, 1903. Cloth. Pp. 312 and 232 Respectively. Price, $1.50 and $1.25. Chicago: The Year Book Publishers.

MICROSCOPY AND BACTERIOLOGY. A Manual for Students and Practitioners. By P. E. Archinard, A.M., M.D., Demonstrator of Microscopy and Bacteriology, Tulane University of Louisiana, Medical Department. Series Edited by V. C. Pedersen, A.M., M.D.,

Instructor in Surgery and Assistant Anesthetist at the New York Polyclinic Medical School and Hospital. Illustrated with 74 Engravings. Cloth. Pp. 210. Philadelphia and New York: Lea Brothers & Co.

DISEASES AND INJURIES OF THE EYE, with Their Medical and Surgical Treatment. By George Lawson, F.R.C.S. Eng., Surgeon-Oculist-in-Ordinary to Her Majesty, the Late Queen Victoria. Sixth Edition, with 249 Illustrations. Revised and, in Great Measure, Rewritten. By Arnold Lawson, F.R.C.S. Eng., Assistant Surgeon to the Royal London Ophthalmic Hospital. Cloth. Pp. 587. Price, about $5. London: Smith, Elder & Co. 1903.

MEDICAL JURISPRUDENCE. A Manual for Students and Practitioners. By Edwin Welles Dwight, M.D., Instructor in Legal Medicine, Harvard University. Series Edited by V. C. Pedersen, A.M., M.D., Instructor in Surgery and Assistant Anesthetist at the New York Polyclinic Medical School and Hospital. Cloth. Pp. 249. Philadelphia and New York: Lea Brothers & Co.

FIRST PRINCIPLES OF OTOLOGY. A Text-Book for Medical Students. By Albert H. Buck, M.D., New York City, Clinical Professor of the Diseases of the Ear, College of Physicians and Surgeons. Second Edition. Cloth. Pp. 216. Price, $1.50 net. New York: Wm. Wood & Co. 1903.

DEPARTMENT OF THE INTERIOR. Bureau of Government Laboratories. Biological Laboratory. A Preliminary Report on Trypanosomiasis of Horses in the Philippine Islands. By W. E. Musgrave, M.D., and Norman E. Williamson. Paper. Pp. 26. Manila Bureau of Public Printing. 1903.

GYNECOLOGY. A Text-Book for Students and a Guide for Practitioners. By William R. Pryor, M.D., Professor of Gynecology in the New York Polyclinic Medical School. 163 Illustrations in the Text. Cloth. Pp. 380. Price, $3.50. New York and London: D. Appleton & Co. 1903.

TRANSACTIONS OF THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION. Volume XV. Fifteenth Session, Held at Cincinnati, Ohio, Nov. 11, 12 and 13, 1902. Edited by W. D. Haggard, M.D. Cloth. Pp. 444. Published by the Association, 1903.

REPORT OF WORKING PARTY No. 1, YELLOW FEVER INSTITUTE. A Study of the Etiology of Yellow Fever. By Herman B. Parker, George E. Beyer and O. L. Pothier. March, 1903. Paper. Washinton: Government Printing Office. 1903.

MY CHILD AND I. In Sickness and Health from Pre-natal Life Until Sixteen. By Mrs. F. L. S. Aldrich, M.D., Member of the American Medical Association. Cloth. Pp. 429. Price, $1.50. Philadelphia: P. W. Ziegler & Co. 1903.

THE ANNUAL REPORT OF THE DEPARTMENT OF THE INSANE OF THE PENNSYLVANIA HOSPITAL, for the Year Ending April 23, 1903. Paper. Pp. 37. Philadelphia. 1903.

HYGIENIC LABORATORY BULLETIN No. 9. Presence of Tetanus in Commercial Gelatin. By John F. Anderson. Paper. Pp. 6. Washington: Government Printing Office. 1902.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, July 18, 1903:

Bushnell, George E., major-surgeon, is relieved from duty at Fort Logan, and will proceed to Fort Bayard and report at the U. S. General Hospital at that place for duty.

Crosby, William D., major-surgeon, is granted leave for one month.

Parkham, Wallace E., contract surgeon, granted leave until June 2, is granted an extension for one month.

Ten Eyck, Benjamin L., major-surgeon, is directed to report to Major-General John C. Bates, president of the Army Retiring Board, at Chicago, Ill., for examination by the board. On the completion of his examination, Major Ten Eyck will return to his proper station.

Trenholtz, Clarence A., contract surgeon, is relieved from further duty in the Department of the Columbia and, on the expiration of his present leave, will proceed to Fort Apache for duty.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended July 25, 1903:

Medical Director J. C. Boyd, commissioned medical director, with rank of captain, from June 20, 1903.

Surgeon E. O. Huntington, detached from the *Maine* and ordered to the Naval Hospital, Navy Yard, New York, for treatment.

Surgeons R. K. Smith, A. W. Dunbar, A. Farenholt, C. P. Bagg, E. J. Grow, M. S. Elliott, commissioned surgeons, with the rank of lieutenant-commander, from March 3, 1903.

P. A. Surgeon R. W. Plummer, ordered to the *Maine*.

Asst.-Surgeons C. E. Ryder and J. A. Randall, appointed asst.-surgeons, with rank of lieutenant, junior grade, from June 26, 1903.

Surgeon C. P. Kindleberger, ordered to the *Independence*.

Asst.-Surgeon A. Stuart, granted sick leave for two months.

Surgeon G. P. Lumsden, detached from the Naval Station, Port Royal, S. C., August 1, and ordered to the Torpedo Station, Newport, R. I.

Surgeon R. M. Kennedy, detached from the Torpedo Station, Newport, R. I., and ordered to the *Dixie*.

A. A. Surgeons A. H. Wise and C. T. Grayson, appointed acting asst.-surgeons, with rank of lieutenant, junior grade, from July 14, 1903.

A. A. Surgeon P. L. Cocke, detached from the *Chesapeake* and ordered to the Naval Hospital, New York, for treatment.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended July 23, 1903:

Assistant Surgeon-General A. H. Glennan, to proceed to Reedy Island quarantine for special temporary duty.

Assistant Surgeon-General L. D. Williams, granted leave of absence for seven days from July 18.

Surgeon J. H. White, granted extension of leave of absence for one month from August 2.

P. A. Surgeon E. K. Sprague, granted leave of absence for ten days from July 22.

P. A. Surgeon Taliaferro Clark, granted extension of leave of absence for fourteen days from July 20.

P. A. Surgeon H. B. Parker, to report to Assistant Surgeon-General H. D. Geddings for temporary duty.

A. A. Surgeon B. F. Duke, granted leave of absence for two days.

A. A. Surgeon S. C. Leonhardt, granted leave of absence for thirty days from September 1.

Pharmacist C. W. Stephenson, granted leave of absence for twenty-three days from August 3.

Pharmacist G. W. Iitis, granted leave of absence for seven days from July 15, 1903, under paragraph 191 of the Regulations.

RESIGNATION.

A. A. Surgeon S. C. Leonhardt, resigned, to take effect Oct. 1, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended July 24, 1903:

SMALLPOX—UNITED STATES.

Colorado: Denver, June 18-July 11, 15 cases.

Illinois: Chicago, July 11-18, 1 case; Danville, July 11-18, 1 case.

Indiana: Indianapolis, July 11-18, 1 case.

Louisiana: New Orleans, July 11-18, 3 cases.

Massachusetts: Fall River, July 11-18, 9 cases.

Michigan: Detroit, July 11-18, 3 cases; Port Huron, July 11-18, 2 cases.

Mississippi: Natchez, July 4-11, 1 case.

Missouri: St. Louis, July 4-11, 6 cases.

Nebraska: South Omaha, June 1-30, 6 cases.

New Hampshire: Manchester, July 11-18, 2 cases.

Pennsylvania: Carbondale, July 14-21, 1 case; Philadelphia, July 11-18, 24 cases, 14 deaths; Pittsburg, July 11-18, 29 cases, 8 deaths; Norristown, July 11-18, 1 case.

Ohio: Cincinnati, July 10-17, 4 cases; Cleveland, July 11-18, 1 case.

South Carolina: Charleston, July 11-18, 6 cases, 2 deaths.

Wisconsin: Milwaukee, July 11-18, 2 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, June 20-July 4, 5 cases.

Belgium: Antwerp, June 27-July 4, 7 cases, 4 deaths; Brussels, June 27-July 4, 5 deaths; Ghent, June 20-July 4, 3 deaths.

Canada: Winnipeg, July 11-18, 1 case.

China: Hongkong, May 23-30, 1 death; Shanghai, June 6-13, 1 death.

Colombia: Bocas del Toro, June 30-July 7, 2 cases, 1 death.

Great Britain: Birmingham, July 4-11, 1 case; Dublin, June 27-July 4, 9 cases, 1 death; Leeds, July 4-11, 7 cases, 1 death; Liverpool, to July 11, 44 cases, 3 deaths; London, July 4-11, 4 cases; Manchester, June 27-July 4, 9 cases; Newcastle-on-Tyne, June 27-July 4, 1 case; Nottingham, June 27-July 4, 2 cases.

India: Bombay, June 16-23, 21 deaths; Calcutta, July 13-20, 4 deaths; Madras, July 13-19, 1 death.

Japan: Formosa, April 1-May 31, 7 cases.

Mexico: City of Mexico, June 28-July 5, 7 cases, 3 deaths.

Russia: Moscow, June 20-27, 3 cases; Riga, April 1-30, 28 deaths; St. Petersburg, June 27-July 4, 18 cases, 1 death; Warsaw, June 13-27, 6 deaths.

Spain: Barcelona, June 20-July 4, 4 deaths.

Turkey: Smyrna, May 24-June 14, 3 deaths.

SMALLPOX—INSULAR.

Philippines: Manila, May 16-June 13, 13 cases, 9 deaths.

YELLOW FEVER.

Colombia: Panama, July 6-13, 3 cases, 1 death.

Costa Rica: Limon, July 2-9, 3 cases, 2 deaths.

Mexico: Cardenas, July 10, 1 death, imported from Tampico; Coatzacoalcos, June 27-July 4, 2 cases, 4 deaths; Merida, July 12, present; Progreso, July 12, present; Tampico, June 27-July 11, 61 deaths; Vera Cruz, June 27-July 11, 64 cases, 21 deaths.

CHOLERA—INSULAR.

Philippines: Manila, May 16-June 13, 127 cases, 112 deaths; Provinces, May 16-June 13, 2,463 cases, 1,718 deaths.

CHOLERA—FOREIGN.

India: Calcutta, June 13-20, 34 deaths, sporadic.

Straits Settlements: Singapore, May 30-June 6, 1 death.

Turkey in Asia: Beytarie, June 6-13, 26 cases, 23 deaths; Kara, June 8-14, 13 cases.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 24-25, 2 deaths.

Philippines: Manila, May 16-June 13, 19 cases, 19 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, May 17-30, 19 cases; Natal, May 10-16, 5 cases.

China: Amoy, May 8-June 13, 525 cases.

India: Bombay, June 16-23, 92 deaths; Calcutta, June 13-20, 31 deaths; Mauritius, June 11-18, 2 cases.

RECENT INVESTIGATIONS BEARING ON INFECTIOUS DISEASES OF UNKNOWN ETIOLOGY.

LUDVIG HEKTOEN, M.D.
CHICAGO.

There is a number of transmissible diseases, both human and animal, some of them exquisitely contagious, the causes of which are still unknown, notwithstanding the most careful search. Of the human diseases belonging to this group I would mention especially scarlet fever, measles, chicken-pox, yellow fever, typhus fever and hydrophobia. Smallpox and vaccinia may also be left here for the present. Of the animal diseases of this group the most important are foot and mouth diseases, peripneumonia, bovine pest, sheep-pox (clavelée), chicken-typhus or chicken-pest, "horse sickness" and epithelioma contagiosum of fowls. The "mosaic disease" of the tobacco plant ("Mosaik oder Fleckenkrankheit des Tabaks") may be given as an example of a contagious plant disease of unknown etiology.

THE INFECTIOUS NATURE OF THE DISEASES DISCUSSED.

In discussing the probable nature of diseases of this kind perhaps the first question to arise will be, "What evidence is there that they are caused by living, infectious organisms?"

In the first place, the demonstration that many of the diseases mentioned may be inoculated successively from animal to animal indicates that it concerns living virus capable of reproduction, and that the diseases in question are true infections, and not intoxications. There are few known poisons, indeed, of such virulency that intoxication is produced by transferring small quantities of the organs or fluids of a poisoned animal to a healthy animal. White mice may be inoculated with tetanus by injecting into the peritoneal cavity a small quantity of the blood of a horse or of a human being suffering with tetanus, but it is not possible to produce tetanus in a progressive series by inoculating other mice with the blood or tissue of mouse No. 1. Now, the toxin of tetanus is one of the most powerful yet known. In 1893 Nicolas[1] reported the production of human tetanus by the accidental inoculation of a small quantity of tetanus toxin. This occurred on a much larger scale in St. Louis, and Bolton, Fisch and Malden[2] found that the serum of a horse in the period of incubation preceding tetanus may contain enough tetano-toxin to produce fatal tetanus in children when injected in the quantities contained in curative antidiphtheria serum. Bolton and Fisch[3] found no free tetano-toxin, however, in the blood, spinal fluid and other tissues of the children so infected with tetanus. They also showed that in horses the development of tetanic symptoms coincides with the disappearance of toxin from the blood. There is no evidence whatever that a purely toxic disease like this can spread directly from patient to patient in the manner characteristic of most of the diseases just mentioned.

Perhaps the most striking experiment showing the inoculability of an infectious disease of unknown etiology is that of Loeffler and Frosch[4] with the filtered contents of the vesicles in foot and mouth disease of cattle: .02 c.cm. of this fluid, freed from visible bacteria and cells by filtration, were injected into animal No. 1, which became sick in a typical manner; the same quantity of similar material similarly treated was transferred from animal No. 1 to animal No. 2, in which there was again produced the same disease; this was carried on successively from animal to animal through a series of six members. Loeffler and Frosch estimate that the sixth animal received less than a two-billionth part of the original quantity of lymph. Inasmuch as .000002 c.cm. of the fresh lymph is not infectious, the only explanation that can be offered in this case is that the virus or cause of foot and mouth disease is a living one capable of proliferation.

Similar experiments, but on a smaller scale, by König indicate that the "mosaic disease" of the tobacco plant is caused by a living, reproducing, infectious agent.

The facts observed in connection with variolation and vaccination, and the spontaneous communicability of smallpox, leave little room for the conception of any other etiologic agent than a living one capable, under favorable conditions, of rapid multiplication. The fact that the quantity of pus was of no import in securing the development of good pustules in smallpox inoculation was used by Linnæus in the middle of the eighteenth century as evidence in favor of his theory that contagious diseases are caused by "animalcula infinite parva." Wasielewsky secured active vaccine material after successive inoculations from cornea to cornea of no less than forty-six rabbits—a result that certainly indicates multiplication of the virus at the points of inoculation.

In the case of scarlet fever, measles, syphilis, typhus fever and yellow fever, peculiar difficulties present themselves to experimental investigation because of the lack of susceptible animals, but the pronounced contagiousness of nearly every one of these diseases leaves no room to doubt their infectious nature. And in the case of yellow fever the epochal investigations of Reed, Carroll

4. Centralbl. f. Bakt., 1898, xxiii, 371-391.

and Agramonte have shown that the cause of the disease occurs in the blood, whence it is conveyed to susceptible persons by the blood-sucking mosquito, *Stegomyia fasciata.*

Is there any evidence that transmissible diseases are caused by enzymes? Now it has been suggested that some of these diseases may be caused by enzymes that act catalytically, and not by virtue of any toxicity of their own. We can understand how enzymes might cause epidemic-like diseases after the manner of certain intoxications of exotic origin, and further, that enzymes may play an essential rôle in the pathogenesis of the diseases, but there is, after all, no evidence at hand that enzymes alone, entirely independently of living organisms as their source, can cause transmissible diseases, like measles, foot and mouth disease and yellow fever.*

As yet we are hardly prepared to receive the hypothesis that certain contagious and communicable diseases are caused by enzymes or other substances that are not directly traceable to living matter—the theory of the contagium vivum has proven itself too heuristic to be abandoned lightly in favor of another hypothesis without analogy and so far insusceptible of demonstration. After all, the continuous metabolism and the power of reproduction characteristic of living matter explain most satisfactorily at present the nature of the causes of the transmissible diseases like these now discussed.

WHAT, THEN, MAY BE SOME OF THE REASONS THAT THE ORGANISMS OF THESE DISEASES HAVE NOT BEEN DISCOVERED?

1. *Incultivability.*—Perhaps the most generally accepted explanation offered of the failure to secure artificial cultures of the organisms that we may suppose cause the diseases in question is that they are of protozoan causation, because of the failures until very recently to grow protozoa. But there are numerous bacteria that refuse to grow on any of the various culture media now available. The bacillus of leprosy, the spirillum of Obermeyer, and leptothrix may be cited as examples of bacteria of well-known morphology that refuse to grow on our media. And then Novy, before the Section of Pathology and Bacteriology of the New Orleans meeting of the Association, demonstrated successful cultures of rat trypanosoma on agar and defibrinated rabbit's blood, so that it is now clearly shown for the first time that it is possible to cultivate pathogenic protozoa. Hence the failure of artificial culture experiments does not mean much as regards either the nature of a given virus, or as to its absence or presence in a given material. The peculiarities in regard to cultural substratum and other conditions necessary for the growth of the bacillus of tuberculosis, the gonococcus, and the bacillus of influenza serve as illustrations of the ingenuity required in order to meet the wants of many pathogenic bacteria. Now it may be that the microbes of measles and the other diseases mentioned are obligate parasites in the strictest sense, and that cultures are obtainable only by natural growth in the fluids and tissues of infected persons and animals. Thus it was by a combination of natural and artificial conditions that Nocard and Roux[5] first obtained evidences of actual growth of the organism of infectious peripneumonia of cattle, namely, by the use of collodion sacs filled with bouillon and serum, and inserted after being inoculated with infectious peripneumonic lymph into the abdomen of rabbits and cows. These cultures *in vivo,* thus surrounded by a diffusible membrane that permitted a ready molecular exchange between the enclosed and the surrounding fluids, soon gave evidence of growth by the increased infectiousness and clouding of the medium, microscopic examination of which showed forms so minute that with the highest obtainable magnification no definite idea as to their exact morphology could be obtained. This organism, therefore, is considered as on the border line between the visible and invisible. Eventually Nocard and Roux obtained subcultures in Martin's peptone bouillon mixed with a small quantity of rabbit's or cow's serum (1-20), and on agar mixed with this bouillon-serum.

Again, in the case of diseases that only affect man it is not without range of possibility that the failure of our artificial cultures made with infectious material is apparent, and not real. Growth may occur invisibly, but in the absence of susceptible animals even this perhaps somewhat remote possibility can not be settled by means of inoculations. On the other hand, it may be urged that if unknown viruses actually grow on culture media the resulting growth or colonies ought to be visible, as in the case of the virus of peripneumonia, even if the individual organisms are too small to be seen, or invisible for other reasons. In liquid media turbidity or other recognizable evidence of growth would be expected did growth actually occur.

The occurrence of diseases of this character among animals and in plants is of the greatest advantage to the experimental study of the many difficult problems that here confront the investigator. This makes it possible to subject infectious material containing the essential cause to various experimental procedures and then to test the result by means of carefully controlled inoculations of animals.

It remains to be seen whether any of the unknown viruses possess sufficient reducing power to enable one to detect their presence in certain mixtures by means of the bioscopic test devised by Neisser and Wechsberg, and of similar methods. Neisser and Wechsberg's bioscopy is based on the reducing power of living matter by virtue of which it secures the oxygen necessary for its metabolic activities. The test as recommended by them is made by adding sufficient methylene blue to distinctly color a suitable mixture containing cells or bacteria and then excluding the air by means of paraffin. Reduction is marked by decolorization of the fluid, the methylene blue on losing oxygen being changed into leucomethylene blue, which has no color. I have found that a convenient method of making this reaction with liquid cultures and other mixtures is to use glass pipettes drawn out thin on each side of a larger oblong chamber. These are easily sterilized, the fluids are readily drawn in by means of suction, after which the glass may be sealed off on each side of the chamber by applying heat to the thin portions. The tubes are then placed in the incubator. Joest[6] reports that

* The idea that ferments may cause contagious diseases is, of course, not of recent date. In 1878 Henry M. Lyman (Chicago Medical Journal and Examiner, 1878, xxxvii, 689), for instance, suggested that in ferments the molecules are in such rapid action as to modify the modes of motion in organized bodies or the products thereof, and that deviations from the normal furnish the ferments of hydrophobia, glanders, vaccinia, smallpox, measles, etc. Variations in the stability of molecular equilibrium would explain, he says, the variable intensity of infection in typhoid fever and other diseases as well as the fatal persistence with which an obstetrician may carry infection with him by virtue of fermentation in his own person.

5. Ann. de l'Institut Pasteur, 1898, xii, 240-262 and 785-798.

6. Centralbl. f. Bact., 1902, xxxi, 375.

his tests of the reduction properties of the virus of foot and mouth disease by the bioscopic method gave negative results. Further experiments are warranted, and by suitable controls the influence of reducing chemical substances may be excluded, at least in many cases. It is possible that in this way some clew might be obtained as to the presence of living substances that hitherto have eluded search. Numerous reduction experiments with the blood and blood serum of scarlet fever patients have so far not yielded any positive results in my hands.

2. *Mixed or Symbiotic Infections.*—The possibility that some of these diseases may be the result of mixed infection is another conceivable reason for the failures to isolate the specific cause, the search for which so far has been conducted, for the most part at least, on the theory that it concerns single organisms. It is conceivable that two organisms may so influence each other by symbiosis as to change materially the nature of the metabolic products from that characteristic of the organisms when growing alone. In this way non-pathogenic organisms might produce toxic substances with definite pathogenic properties, or the qualities of an originally pathogenic organism might be radically changed. The recent application by Welch of Ehrlich's lateral chain theory to bacteria, with a view to a better explanation of the production of bacteriogenous cytotoxins in infections, may prove helpful also in this case. This conception enables one to understand how it can be possible for an organism under the influence of stimuli from the body in which it has become lodged to produce by its receptor mechanism intermediary bodies that when attached to the cells of the host and complemented, would produce most serious symptoms and lesions. Particularly difficult of detection would be organisms that are pathogenic only in man. Even artificial culture would not necessarily solve the problem. From the facts at hand in regard to smallpox and scarlet fever it seems safe to conclude that in the majority of fatal cases death is not due to the original disease, but to secondary, mixed general infections with streptococci which are demonstrable in large numbers in the blood and in the internal organs of almost every fatal instance of these two diseases. In measles secondary local and general infections also play a most important part in the severe and fatal cases. Nothing definite is known in regard to mechanism whereby these secondary and dangerous infections are established.

It is possible, too, that the hiding place of the pathogenic agent may not have been detected. It may remain localized in some part of the infected body, where it manufactures the toxic substances that cause the outbreak of the general symptoms by which the disease is recognized.

3. *Unstainability.*—It has been pointed out, too, that perhaps some of these infectious agents are unstainable by our present methods. There may be no chemical affinity between the stains used and the protoplasm, or it may be physically impossible for the molecules of the stains to make their way in the interstices of the cytoplasm of the organisms.

4. *Ultramicroscopic Size.*—Furthermore, there is the possibility that certain organisms, whatever their nature, are too minute to be seen. Pasteur, in 1881, suggested that the virus of hydrophobia is too small to be seen. Now there is a definite limit to visibility. Helmholtz showed that because of dispersion of light at the margins of minute objects, those of a diameter less than 0.2 mikron can not be rendered visible in the usual sense. The influenza bacillus is generally mentioned as one of the smallest of bacteria. The diameters are given as about 0.4 mikron broad by 0.8 to 1.2 mikrons long. If it were four to five times smaller it could not be seen. The organism of peripneumonia is so small that it is just visible under the best microscopes, and it may be spoken of as on the border line between the visible and invisible. This leads us to discussion of the question of the existence of ultramicroscopic pathogenic agents, which until a few years ago were objects only of theoretic interest, but which now are receiving much study.

FILTRATION EXPERIMENTS.

For some time various forms of mineral filters—porcelain, infusorial earth, etc.—have been found useful in securing filtrates free from bacteria and other organisms; indeed, filtration is one of the classical methods of sterilization, and recent experiments with the filtration of infectious material from diseases of unknown etiology have given some very interesting and valuable results. A brief review of some of the recent work in this field is, therefore, in order.

1. *Smallpox and Vaccinia.*—So long ago as 1868 Chauveau[7] made the first experiments to demonstrate the corpuscular nature of vaccine virus. His efforts at filtration did not succeed in separating any pathogenic elements from the serum probably because of the imperfect form of filters used, but by carefully devised diffusion experiments he found that the active part of the virus settled at the bottom of his mixtures. In 1891 Schulz and Weil separated by filtration the active parts of vaccine virus from the fluid portion, and since then several other investigators, among them Gorini and Wasielewsky, have confirmed this demonstration. The latest experiments in the filtration of vaccine and smallpox virus are those of W. H. Park.[8] In order to destroy the epithelial cells which might contain the virus and hinder it from passing through the filter, he first crushed the material with fine sand under a pressure of twenty pounds to the square inch, but even now vaccine and smallpox virus failed to pass through Chamberland and Berkefeld filters. The process in itself did not destroy vaccine virus. Hence it may be regarded as definitely settled that the virus of vaccinia and variola is not filterable, as that word is now understood.

Wasielewsky[9] has showed that Guarnieri's intracellular vaccine bodies (*Cytoryctes vaccinæ*), the formation of which can be followed in the corneal cells of the rabbit after the introduction of vaccine virus, do not develop when filtrates of vaccine virus are used. As stated, Wasielewsky successfully inoculated vaccine virus from cornea to cornea through forty-six generations, a fact that virtually proves proliferation of the virus at the site of inoculation when one considers the minute quantity originally introduced. Active vaccine for children and calves was obtained from the last animal in the series. Somewhat similar bodies occur in the skin lesions of variola and vaccinia; and so far it is claimed that it has not been possible to induce such bodies to appear within the cells under any other conditions than vaccinia and variola. Any one reading carefully Wasielewsky's article can not but acknowledge that he builds a strong chain of evidence in favor of the etiologic rôle of the vaccine bodies of Guarnieri in vaccinia, but it should be remembered that Hückel,[10] in an elaborate study, reaches the conclusion that these bodies are the result

10. Ziegler's Beitrage, Supplementheft, ii, 1898.

of a special form of cell degeneration caused by vaccine virus only.

But this is not the proper place to discuss fully all recent work on the cause of smallpox and vaccinia. The announcement by Councilman, Brinkerhoff and Magrath, and by Tyzzer, of the presence of certain bodies interpreted by them as development cycles of a protozoan organism, in the lesions of smallpox and vaccinia, represents the latest effort toward the demonstration of the cause of these diseases. The failure of the virus of smallpox and of vaccinia to pass through filters is in harmony with the interpretation that the various bodies described in the lesions of these diseases represent their causative agent.

2. *Hydrophobia.*—The failure to demonstrate the cause of hydrophobia led Pasteur to suggest that it might be too small to be seen. It is currently stated that the virus of hydrophobia does not pass through mineral filters, but Remlinger and Riffat-Bey[11] claim to have passed it through Berkefeld filter 5. Further observations are necessary.

3. *Bovine Peripneumonia.*—This disease is characterized by the accumulation of serous fluid in the interstitial tissues of the lungs. The injection of some of the fluid under the skin is followed by an enormous edematous infiltration and death of the animal. The fluid of such infiltrations is clear, free from distinctly visible corpuscular elements, and bacteriologically sterile when inoculated on the ordinary media. As stated, Nocard and Roux succeeded in demonstrating the presence of an organism by means of intra-abdominal sacs. They found, further, that by diluting the serous fluid with twenty to thirty times its volume of water it becomes possible to secure virulent filtrates by passing through Berkefeld or Chamberland filters. The microbe of peripneumonia does not pass through Chamberland B cylinders. Smears of the cultures obtainable in serum-bouillon and serum-bouillon-agar show forms so minute and indistinct that this microbe marks the border line between the visible and the ultramicroscopic. Its cultures in bouillon are characterized by slight cloudiness, and on agar exceedingly minute colonies develop.

4. *Foot and Mouth Disease.*—The infectious fluid of the aphthous vesicles of foot and mouth disease is limpid and free from visibly formed elements other than cells. Loeffler and Frosch found that this fluid diluted with water remained virulent after passing through Berkefeld filters that refused to pass *B. fluorescens.* These filtrates were bacteriologically sterile and free from recognizable corpuscles. But Kitasato filters, which have smaller pores, did not allow the virus to pass into the filtrate.

5. *Yellow Fever.*—So far as I know the only human disease up to the present time shown by actual experiment to be caused by a virus capable of passing through a filter that generally delivers bacteria-free filtrates in the ordinary sense, is yellow fever. The investigations of Reed, Carroll and Agramonte[12] show "that yellow fever may be produced in non-immune persons either by the bite of the mosquito (genus stegomyia) that has previously been permitted to fill itself with the blood of a patient suffering from yellow fever during the first three days of the attack, or by the subcutaneous injection of a small quantity of blood (0.5 to 2 c.c.) from the general circulation of such a patient during the active stage of this disease." Microscopic search, however, for the specific agent in the blood of patients and in infected mosquitoes in which the micro-organism no doubt undergoes an evolution thus far had been entirely negative.* Carroll then produced yellow fever in two persons by the bite of infected mosquitoes, and with the blood of one of them, withdrawn at the beginning of the third day of illness, the following experiments were made: A quantity of serum, diluted one-half with sterile-distilled water, was passed through a sterile Berkefeld filter, which, on special test, was found to hold back ordinary bacteria; 3 c.c. of this filtrate was injected subcutaneously in three American soldiers, two of whom developed typical attacks of yellow fever, the result in the third being negative. Subcutaneous injection of 1.5 c.c. of blood from one of the cases of yellow fever thus produced gave rise to a typical attack in the soldier who remained well after the injection of 3 c.c. of filtered, dilute serum eight days previously. A subcutaneous injection of 0.75 c.c. of unheated, partially defibrinated blood (the same that furnished the serum for filtration) produced yellow fever in a Spaniard, but in three cases the injection of 1.5 c.c. of the partially defibrinated blood, heated for ten minutes to 55 C., failed to have any pathogenic effect. From these interesting and important results Reed and Carroll drew the conclusions that yellow fever is caused by an agent so minute that it passes readily through the pores of a Berkefeld filter, and that this agent, which they regard as ultramicroscopic, is rendered harmless by heating to 55 C. for ten minutes. Against the view that the yellow fever in these cases was caused by toxin, they urge especially the production of the disease in a third individual, since it would be difficult to understand how so great dilution of toxin would be capable of causing an attack.

6. *Exudative Typhus of Chickens, or Chicken-Pest.*—In certain parts of Italy, especially the northern, in Tyrol and also elsewhere, there occurs a devastating disease among chickens which has been recognized as a distinct disease for about ten years, and which recently has been studied more definitely by Centanni,[13] Maggiora and Valenti,[14] and Lode and Gruber.[15] In order to distinguish the disease from chicken cholera—rabbits are susceptible to chicken cholera, but refractory to this disease—and to give it a non-committal name, Centanni proposes to call it birdpest (Vogelpest), while Maggiora and Valenti, for historical reasons, favor the term "exudative typhus." The clinical and anatomical picture is not unlike that of ordinary chicken cholera and other virulent general infections. It is a disease from which recovery does not seem to take place. The sick animals become quiet; soporose, the comb generally violet in color. (Hence the name Kyanolophiea suggested by Lode and Gruber.) In severe cases the disease may be hemorrhagic. There may be exudative pericarditis,

* While this article is passing through the press there has come to hand the report by Parker, Beyer and Pothier of the United States Public Health and Marine-Hospital Service (Yellow Fever Bulletin No. 13), in which the discovery is announced of the development of a sporozoan organism—*Myxococcidium stegomyiæ*—in mosquitoes (stegomyia) that have filled themselves with the blood of yellow fever patients. The importance of this discovery, if confirmed, as regards the causation of yellow fever is apparent at once, and it may be that the results of the filtration experiments of Reed and his colleagues will be explained by the presence in the blood of yellow fever patients of some ultramicroscopic developmental stage of *Myxococcidia stegomyiæ.*

pleuritis and peritonitis, often of a gelatinous character, but the anatomical picture is exceedingly variable. Microscopically, there is an intense myocarditis, exudations in the lungs, marked degeneration in the liver and kidneys, and more or less enteritis, all being changes that indicate an acute, violent, general infection.

(To be continued.)

REQUIREMENTS FOR ADMISSION TO MEDICAL SCHOOLS.

N. S. DAVIS, Jr., M.D.
CHICAGO.

During the last decade no question has excited more discussion among medical teachers than what should be the requirements for admission to college. These requirements have been steadily advanced, but as yet there is no settled conviction as to how far they shall be advanced. In other words, it has not been determined what are the ideal entrance requirements.

In this country the existing requirements vary from what must be studied to complete the eighth grade of the grammar school to what is embraced in the complete curriculum of a college of arts or sciences. At least, the mean between these extremes is reached by all of the best schools of the country. It will not be long before a satisfactory completion of the subjects of a four-year high school course will be demanded for admission to all medical colleges, because the laws of many states under which physicians are licensed to practice now demand this amount of general education. Schools which do not meet the standard set by these laws are not in good standing, and their graduates can practice their profession only in a limited portion of the country.

Entrance requirements are needed (1) to make sure that medical students and graduates shall have enough general education to enable them to mingle with the best people of the land on an intellectual level; (2) to make sure that such subjects have been thoroughly learned as are essential to an understanding of what is taught in a medical curriculum.

It may be said at once that to meet the first of these needs a full college course in arts or science or its equivalent should be taken, but it must not be forgotten that four years devoted to the study of medicine is as liberalizing and as sure to give mental culture as the same amount of time in a school of science, provided the same preliminary education has been had. This fact seems to have been forgotten or overlooked by many who have recently discussed the subject.

In regard to the second need, it may be urged that many of our medical leaders had only a grammar school course, and had no difficulty in understanding the subjects of a medical curriculum and of keeping *au courant* with the advances made in their profession. It must not be forgotten, however, that conditions have changed; that the medical curriculum contained few subjects fifty, nay even thirty, years ago, and that their literature was small, for of them comparatively little was known. Moreover, a kind of preparation is required for the laboratory methods by which medicine is taught to-day that was not formerly. For instance, a boy who has never worked in a laboratory, who has not been taught to reason from what he sees, or even to use his eyes accurately, can not get from the work of the first year of a medical course, as it is now taught, what he should, for much time will be lost in teaching him how to do these things.

It is also necessary that certain subjects be required of those about to study medicine, because many of the more recent discoveries in the fundamental subjects of a medical course have been made possible by earlier but recent discoveries in ancillary sciences. These sciences, therefore, must be studied before medicine is.

I believe that graduates of our best high schools and preparatories have as much general education as need be demanded. They should be capable of expressing themselves clearly and correctly in their mother tongue; should have mastered the tools by which an education is to be acquired; should have powers of mental concentration and enough varied information to be appreciative of all kinds of knowledge. However, only the courses offered by colleges of arts or sciences furnish the kind and grade of instruction which is requisite for an understanding of portions of a modern medical curriculum; therefore, at least a part of a college course must be required for entrance to the medical college. President Hadley has said that just such subjects as are necessary to understand medicine as it is now being taught, and no more or less, should be required. This is pedagogically correct. Therefore, I do not feel in full sympathy with those schools which have nominated as their entrance requirement an A.B. or B.S. degree, or a certificate of having completed one or two years of a course leading to such degree. A bachelor's degree or a fixed period of time in college does not necessitate a proper preparation for the study of medicine, for a student to-day may graduate from any of the leading colleges of arts without having taken chemistry, physics or any biologic course. Such a graduate is no better prepared for medicine than when he entered the college of arts, except that he is more mature and better trained to do hard mental work.

Moreover, the degrees of B.S. and A.B. mean very different things, according as they are obtained from one of the small and inadequately equipped degree conferring institutions or from one of the great universities of our land. For these reasons the indefinite requirement of so many years in a college of arts or science is not satisfactory.

The following subjects are the ones of college grade which it is most important for students and graduates of medicine to know: Inorganic chemistry and qualitative analysis; mechanics, light, heat and electricity; general biology; some comparative anatomy, particularly of vertebrates; German and French, and such botany as will acquaint them with the more important groups of plants; experimental psychology and logic.

These subjects are not all equally important, and if medical schools which now require four years of high school work for entrance are to gradually increase their requirements, the most important should be added first.

A medical curriculum can not be properly graded until chemistry and physics are demanded of those who undertake it, for they are so essential to an understanding of physiology and physiologic chemistry. Therefore, they should be among the first required college courses.

Harvard demands of those entering the medical school a complete course in a college of arts or science, but specifies that they must have studied chemistry. Johns Hopkins goes further in requiring physics, some biology, and German and French. Other medical colleges which have required a part of a bachelor's course have not specified these or other subjects.

General biology is almost as important as chemistry and physics. However, the information which this study insures one is not of so much use as is the

training in a biologic laboratory, for this furnishes the student of anatomy and physiology with such skill as will enable him at once to get the most that is possible out of these subjects as they are taught in the best university medical schools. A knowledge of comparative anatomy will make human anatomy easier and more interesting. It is not, however, as essential for the beginner in medicine as the subjects just mentioned. For the graduate, French and German are essential, in order to keep abreast of professional progress; therefore, they should be acquired preparatory to medicine. Botany, psychology and logic, like comparative anatomy, make the acquirement of other medical subjects easier and increase the pleasure and interest of the student in them.

If four of the most important of these subjects are added to existing entrance requirements, they will rarely be acquired by students in less than two years in colleges of arts or sciences, for, although in themselves they do not make more than a year's work, the schedules of colleges are so planned that they can not be taken simultaneously; and if all the subjects named were required, a college residence of at least three years would be needed. Almost without exception, therefore, other and less technical subjects will be studied as well.

A change in the entrance requirements of medical colleges which is needed, and which will do more to improve the quality of the student body than almost anything else, is to stop admitting on certificates, and to require of all who enter thorough examinations in a few required subjects.

The ideal course for medical students is a combined one of six years, leading to both the degrees of B.S. or A.B. and M.D., which such universities as Michigan, Northwestern and Chicago have been offering. Three years are spent in Michigan and Northwestern in the college of arts, during which time almost or quite all of the freshman course in medicine is completed. Three years more are spent in the medical school. At Chicago University two years are spent in the arts department and four in the medical. Harvard and Cornell make a seven-year combined course. It is so usual for all the best graduates in medicine to spend eighteen months or two years in post-graduate work that these combined courses should be made no longer than is absolutely necessary, for it is as much a detriment to the beginning practitioner to be too old as to be too young. A combined course should be completed, if possible, when the student is 24 or 25 years old. For many years a longer period of education has been required of students of medicine than for those preparing for other professions, although the emoluments of practitioners are no greater, nor as great, as those which the practice of law makes possible. Therefore, neither preparation for the study of medicine nor the arrangement of subjects in the medical curriculum should be allowed to too greatly prolong the student's period of academic and college work.

Method of Arresting Epistaxis.—Matthews is quoted by the *Journal Méd. de Paris* as advocating a condom for arresting hemorrhage from the nose. (This has been mentioned before.) The condom is oiled and inserted in the nose on the end of a catheter. The latter is then partly withdrawn, and through it the condom is inflated. The outer end is then tied around the catheter, and thus forms a "balloon tampon," which can be easily removed at any time without disturbing the clots, by allowing the air to escape first.

CO-OPERATIVE METHODS FOR IMPROVING THE USEFULNESS OF STATISTICAL CLASSIFICATIONS OF CAUSES OF DEATH.*

CRESSY L. WILBUR, M.D.

Chief of Division of Vital Statistics, Department of State, Michigan, and Medical Referee of the United States Census in Vital Statistics.

LANSING, MICH.

One of the most important matters involved in the administration of a registration office is the selection and proper use of a statistical classification of causes of death. The mortality from various diseases must be known in order that the value of methods adopted by sanitary officers for their prevention and restriction may be appreciated, and it is important for many reasons that accurate and fully comparable statistics of causes of death be published. This presupposes the use of some classification of causes of death.

It may be said that the use of a formal classification is unnecessary, as the causes returned by physicians might be stated in alphabetical order. This would be possible for only the smallest areas of registration, and for short periods of time. For a large city, a state, or for the country as a whole, the number of different terms returned as causes of death would be so numerous that it would not be feasible to give each one a separate line in statistical tables. Even where it has been attempted to make use of the alphabetical arrangement numerous terms have usually been condensed under single titles, so that a method of classification was actually in use. Where this is not the case the statistics may be very misleading, and may give rise to annoying blunders on the part of those consulting them unless they first complete the work of proper statistical compilation that was left unfinished by the registration office. As an amusing instance, I may quote the following from a recent issue of The Journal of the American Medical Association, under the heading, "Clippings From Lay Exchanges":

> Tuberculosis of the lungs carried off twenty-five of the victims of disease last month. Seven others died of tuberculosis and four of phthisis.

It may be well at this point to call attention to the limited sense in which the word "classification" is now employed in this connection. It does not refer to a broad and comprehensive philosophical arrangement of diseases, based on general principles and intended to show the natural or scientific relations of the diseases or causes of death. If this were the object of a statistical classification of causes of death at the present time, it would be necessary to acknowledge failure from the start. No ideal classification fully exhibiting the natural relations of diseases and meeting the demands of all classes of scientific workers is yet possible. The tendency is strongly in the direction of doing away with all so-called "groups" or "classes" of diseases and of placing stress chiefly on the definite meaning and inclusion of the individual titles. "Classification," said Dr. Farr, "is another name for generalization." Our object at the present time in statistical classification of causes of death is to do away with generalization as far as possible. The old statistical groups of "zymotic diseases," "constitutional diseases," "diathetic diseases," and the like, have disappeared, or remain only as belated relics of a former nomenclature. Even the distinction between "general

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

diseases" and "local diseases" can not be considered of any special importance to-day. The boundary is elastic, and a so-called "local" disease of to-day is placed by the advanced pathology of to-morrow among the general infections.

By the adoption of a statistical classification of causes of death, therefore, we mean nothing more than the use of a certain number of titles of diseases, each with a definite inclusion of terms as returned by physicians on certificates of death. For convenience a certain general arrangement is usually followed, as in the International Classification, now in general use in this country. The titles of this system and the detailed list of terms included under each title are given in the Manual of the International Classification, published last year by the United States Census Office.

This classification was reported by Dr. Jacques Bertillon, as chairman of a committee of the International Statistical Institute at the session held in Chicago in 1893. It was the result of a movement for uniformity in statistics of causes of death that had engaged the attention of registration officials and users of mortality statistics for half a century. The Conference of State and Provincial Boards of Health indorsed it at Detroit in 1897, and the American Public Health Association recommended its general use at Ottawa in 1898, and reported a plan for its regular decennial revision by an international commission to meet at Paris in 1900. This recommendation was indorsed by the International Statistical Institute at Christiania in 1899, and the international commission for the first revision of the classification met at Paris, August 18-21, 1900, by invitation of the French government, representatives from twenty-six countries taking part in the sessions. This Section of the American Medical Association adopted a resolution in its favor at Atlantic City in 1900, and it has since been accepted by every registration state, most of the leading cities, the United States Census Office, United States Department of Labor, etc. It has been adopted by Canada, Mexico and by the countries of Central and South America, and has no rival as an international classification.

Its imperfections have never been ignored by the strongest advocates of its general adoption. It is faulty, as are all other systems. The reason for its use lies not in any perfection of the system, but because it was possible by adopting it to unite on a general basis of uniformity. This we have done, and we are now ready, by coöperative work, to amend and improve it, and make it, by means of the periodical revisions that all classifications require, more definite, more practical, more useful in every sense of the term to all who have occasion to employ statistics of causes of death.

How shall this be done? Only by enlisting the aid of all users of mortality statistics, and ascertaining in just what respects the system requires alteration to best serve their wishes.

Here it may be necessary to explain in fuller detail just what are the relations of vital statisticians to the matter of classification of causes of death generally.

The source of information in regard to causes of death is the medical profession. The individual physician who makes a statement on the medical certificate of cause of death in regard to a case that has occurred in his practice makes the first contribution to that mass of data from which come the mortality statistics. The certificate signed by the physician goes into the local registration office and is there recorded. Possibly, if in a city, it may be compiled there, and the mortality statistics accompanying the annual report of the city board of health be derived therefrom. In our state, as in some other registration states, the certificate is next sent to the central registration office at the capital, and is there permanently preserved. It is again compiled, first, for the Monthly Bulletin of Vital Statistics, and, second, after all delayed returns and corrections have been received, for the annual registration report. Lastly, a transcript of this certificate goes to the United States Census Office at Washington, where it is not recorded, but where the information is transferred to the cards employed in the electric tabulating machinery, and it is again compiled—this time for the annual report on mortality now required by law to be prepared by the permanent Census Office. This is the final statistical report, but all alike—the national, state and local compilations—agree in the fact that the original certificate of death signed by the attending physician is the source of all information. The validity of the statistics can not rise above the authority of their source, and, if the original statements of causes of death as made by the physicians are vague, indefinite and full of error, then the statistics must be defective and unsatisfactory to precisely the same degree.

Compilation is that process by which statistics are derived from the mass of individual records, and, for our special purpose, may be limited to the production of the finished tables of causes of death showing their various relations by locality, date of occurrence, age, sex, color, nativity, etc. It should be a colorless medium by which all of the important features of the original returns may be preserved, in condensed form, and nothing should be added to or subtracted from the significance of the original statements.

Here we may note two leading difficulties of compilation. These are, first, the condensation of the extensive list of terms reported by physicians to fit the comparatively short list of titles alone feasible in statistical reports, and second, the selection of the proper title for compilation when two or more causes have been assigned by the physician. These difficulties increase with the mass of returns to be handled, and are more pressing in the larger offices, where the vast mass of causes and complications renders some uniform system of procedure indispensably necessary.

Some idea of the large number of causes reported by physicians may be gained from examination of the Census Manual of the International Classification. Each one of these terms, with the exception of a few translated from the report of the French commission, has been actually returned on a certificate of death by some physician in the United States. And, moreover, any two or three of these terms may occur on a single certificate, and in any combination. If there were only 5,000 different terms, and there are many more than that, then there would be 25,000,000 different binary combinations of those terms possible, or, disregarding the order of the terms, which is seldom important, there would be 12,500,000 combinations of different terms. Practically, such combinations are endless in variety, and yet in the process of compilation all of these 5,000 terms and 12,500,000 possible combinations must be reduced to the exact number of titles in the system selected. In the International Classification there are only 179 titles in the detailed form, and no classification much exceeds this number.

This process of condensation of medical terms under synonymous titles, or the selection of the true cause of death from several causes assigned by the physician, constitutes a large part of the practical work of a regis-

tration office in the treatment of causes of death. To be of value it must be under medical supervision, and yet, from the considerable amount of clerical labor involved, it is rare to find that a qualified medical statistician passes on each individual certificate of death. As a rule, certain principles and methods of procedure are established, and only exceptional cases are referred to expert judgment. Even if competent medical statisticians gave their personal attention to the assignment of each certificate of death compiled in the various offices, there would be numerous differences of practice, and consequent variations in the resulting statistics, unless a comprehensive system of treatment were adopted in all alike.

The adoption of such a system of assignment of individual single terms is the characteristic feature of the International Classification, which renders it superior for general adoption and the promotion of uniformity to any other system now in use. It gives the title to which each individual term is to be assigned. The question of assignment to one title or another, or the formation of new titles, is a proper subject for settlement at the regular decennial revisions, but between the revisions each term has a definite place in the classification, and all offices using the classification put it there. For the use of other systems there is no authoritative guide. A registration office in this country that undertook to employ the English registrar-general's classification might do so, so far as outward form was concerned, but there would be no assurance that the terms received from physicians' certificates were assigned as the registrar-general would assign them. Each office would be a law unto itself, just as in the old days before the adoption of uniform methods under the international classification.

For the treatment of jointly-returned causes of death no systematic method applicable to all classes of returns has as yet been introduced. It is usual in statistical offices to keep a book of practice showing decisions in such cases, and in time precedents may be collected showing the assignments of the most common causes when returned together. Attention was called to the importance of the subject by Würzburger at the session of the International Commission at Paris, and a tabular arrangement showing the preferences to be given individual titles of the classification was appended to the report of the Commission by Dr. Bertillon. This method, however, deals only with the definite titles, not with the numerous terms of varying degrees of accuracy included under the titles, and the judgment of the statistician would often be required as to whether the relative assignments of certain titles should govern the assignments of certain terms included. Many cases, moreover, including some of the most difficult, and practically all of the terms embraced under general or residual titles, are left to unguided individual decision.

Consideration of the difficulties attending this class of decisions and analysis of the process by which a final judgment was usually arrived at have suggested another plan for the systematic treatment of jointly-returned causes, and one which, in addition, seems adapted to the thorough revision of the international classification so that it will most fully meet the wishes of all of its users. This plan is set forth in a circular[1] of the Committee of the American Public Health Association on Demography and Statistics in Their Sanitary Relations.

When a death is returned from two causes, e. g., typhoid fever and valvular disease of the heart, one of these terms must be selected. The death can not be compiled under both typhoid fever and organic heart disease—at least it can not in any present system of classification. Which shall be chosen? Which title will best represent this case in the compiled statistical tables? Which will best serve the purposes of the users of the statistics?

When the terms, as in the example above, are exactly the same as, or fully equivalent to, the titles of the classification, then the question resolves itself into: "Which title is more important?" Different answers may be given to such a question. The sanitarian, regarding typhoid fever as a dangerous communicable disease, and interested in its prevention, wants to know the exact number of deaths from this disease. He cares nothing about organic heart disease, relatively, but says at once: "Put it under typhoid fever." The actuary or medical director of a life insurance company, dealing with such a return, might consider the statement of heart disease the more important. As a matter of fact, the individual might not have succumbed from typhoid fever if the heart had not been affected, and might have lived for many years with the heart affection but for the intercurrent attack of typhoid fever. The clinician, the pathologist, the sanitarian, the actuary—each may have a different opinion. It is the duty of the vital statistician to endeavor to satisfy the wishes of all, as far as possible, and for that purpose it is necessary to ask for the opinion of each class of users of mortality statistics. Such opinions to be available for use must be comparable, and the most obvious way of attaining this object was to ask for numerical answers. "What would you rate the importance of each title on a definite scale, say from 0 to 10?" Then the more important title, as numerically rated for general purposes, should be preferred, no data as to relative duration, primary or secondary occurrence, etc., being available to modify such judgment.

In a similar case, suppose the return to have been "continued fever" and valvular heart disease. Now, "continued fever," stated alone, is compiled under typhoid fever, but there is some uncertainty about it. It can not be considered as fully equivalent to this title. The registrar in estimating its value as compared with the other cause assigned, necessarily considers this fact, and may decide that a doubtful statement of typhoid fever is less satisfactory for compilation than a positive one of organic heart disease. In other words, we consider two factors in deciding every case of independent joint causes, first, the relative importance of the titles to which the terms would be assigned, and second, the validity of the terms as more or less certainly belonging under the titles selected.

Both of these factors are capable of numerical rating on the decimal or other scale. Having rated the importance of each title, and also the validity of each term as related to its title assigned, then the product of these numbers will give a general weighting number or combining number for each term returned on a certificate of death, by means of which the preference to be given in classification, i. e., assignment to titles, is definitely indicated. Provision would necessarily be made for equal rates, but a very large proportion of cases would be decided directly by the combining numbers.

A very practical advantage of such a system is that the combining numbers or weights could be readily in-

1. The circular was presented in connection with this paper, together with some preliminary ratings of titles of the International Classification obtained under it, which showed the usefulness and entire practicability of the system proposed. For copy of the circular, the special blank, with instructions, prepared for rating the titles of the classification and other information inquiry should be addressed to Mr. W. A. King, Chief Statistician of the U. S. Census, Washington, D. C., who is chairman of the American Public Health Association's committee.

serted in an ordinary index of causes, as in that of the Census Manual, without increasing its length by a single page, and that the decisions between any two out of, say 5,000 terms, could be instantly found. Many millions of separate decisions would be thus condensed, which, expressed in any other way, would require many pages to record, and would be a vast, perhaps insuperable labor to frame. And the principle of each individual decision, as made between two independent terms coming before the registrar, would be precisely the same as that derived from his previously recorded numerical judgment, as expressed in a rating.

It is not my intention to urge that the classification of causes of death shall be an entirely mechanical process. To accomplish the best results it must necessarily be conducted under medical direction, and first-hand examination of the original certificates will often disclose valuable suggestions as to the true place of the return in classification. Nevertheless, the most accomplished medical statistician will find cases where his judgment is uncertain, or where, at different times, he may make contrary decisions. A series of rating numbers would then be most useful, and would tend to unify practice. For many offices, however, where the compilation of data is left more or less entirely to clerks who do not possess medical qualifications, the plain and explicit directions available by means of the ratings would be invaluable.

The advantages of such a system for the criticism and revision of the classification are obvious. With each title and each constituent term assigned a definite value in the opinions of the chief users of statistics, it would be merely necessary to lop off titles of little consequence, and to exclude terms of very uncertain validity under the titles to greatly improve the precision and usefulness of the system. In some cases titles of slight precision would have to be retained on account of the large number of returns received under them, but their low value would be forcibly called to attention, and, in time, the physicians might be brought to avoid them. Indefinite terms that now vitiate the statistics of certain causes would be thrown out by this process of sifting, and a thoroughly revised and renovated classification would be the result. It is physically impossible for a commission to consider all of the points that require attention in an ordinary session of a few days, but with the concrete opinion of registrars, clinicians, pathologists, sanitarians and other classes of users of mortality statistics, definitely expressed in advance and capable of numerical analysis, the work of revision should be most complete and satisfactory.

At present all classifications are lumbered to some extent with useless titles. These are titles of little precision, of rare occurrence, or divided more minutely than the accuracy of returns will warrant. On the other hand, some diseases of great importance are lumped together without reference to the very important clinical, pathologic and etiologic distinctions that should be observed. It might be possible, by eliminating titles of small consequence, to obtain statistics of the causes of death of first importance, in all their necessary details, and also to add a selected list of the most important combinations of causes, without exceeding the usual limit of registration reports.

What is needed at the present time is a full expression of opinion on the practical matters relating to the statistical presentation of causes of death from the entire medical profession. The public health workers have begun the task, because the collection and publication of vital statistics is usually a part of the duties devolving upon sanitary administrations, and the preliminary announcement from the committee of the American Public Health Association, indorsed by the committee of the Conference of State and Provincial Boards of Health of North America, shows how the matter has been gone about. Sanitarians and vital statisticians alone can not make this movement a complete success. The interest and help of the entire profession are necessary adjuncts. The clinician, whether practicing in city or country, whether a teacher in a medical school or a private observer, should render aid. The pathologist should consider the questions involved from his point of view. Men devoted to special branches of medicine, as pediatrics, gynecology, surgery, obstetrics, etc., should give the benefit of their experience. The aid of the various special societies should be obtained, and also, through the coöperation of the state societies, with their constituent county organizations, the friendly feeling and interest of the entire medical profession of the country should be secured for this movement to improve the accuracy and usefulness of mortality statistics. Naturally, with this object in view, we come to the American Medical Association, and one of the purposes of the presentation of this paper is to ask the practical coöperation of the Association, by means of a special committee on vital statistics, with the corresponding committees already organized by the American Public Health Association and by the Conference of State and Provincial Boards of Health.

Many years ago a very able committee was appointed by this Association charged with the duty of "preparing a uniform plan for registration reports of births, marriages and deaths; including a nomenclature and classification of causes of death." Members of this committee were Drs. Edward Jarvis, W. L. Sutton, Wilson Jewell, Edwin M. Snow and R. W. Gibbes, and very able reports were presented to the Association at the sessions of 1858 and 1859. The intervention of the Civil War prevented the continuance of their work, and we are just beginning to be ready to-day, after over forty years, to carry out the principles of uniform and effective registration laws and uniform and comparable presentation of statistical data, especially relative to causes of death, that these pioneers of registration work so zealously advocated at that time. We now have the immense advantage of a permanently organized Census Office representing the Federal Government, and prepared to coöperate, and now effectively coöperating with the state and municipal registration offices and with the committees of those organizations that have undertaken to aid in this work. We now have the great additional advantage of a more thoroughly organized and united medical profession, and by its aid, under the auspices of the American Medical Association, these desirable reforms can be rapidly brought to accomplishment. It is time that a committee was again organized by the Association for this purpose, and I trust that your recommendation will be heartily given for this purpose.

DISCUSSION.

Dr. J. S. Fulton, Baltimore—The situation in America was never more hopeful than it is at the present time. We have a Census Bureau, which is a permanent organization. We have an energetic and (I think I may say) an enthusiastic committee working along these lines; and it certainly seems reasonable to hope that we shall, in the course of a few years, reach the individual contributors to the statistics, the physicians who make out the certificates on which the statistics are based.

It is a great pity that our classification must be mechanical. The mathematics of the subject, as Dr. Wilbur says, very clearly show that we can only have a certain number of places for distribution of the causes of death. That necessitates the absolute loss, from certain columns of mortality, of an indefinite number of causes leading to death, and perhaps introduces inevitable error, since we who are the statisticians compiling these data are rather impressed with our own side of the question of assigning position to certificates of death. It was an excellent idea in the Census Bureau to address inquiries to a great many men in the leading specialties in medicine, asking them to express opinions or give definitions of the various titles in the international classification. I think in that way we can eliminate our own particular bias; or, if we can not eliminate it, we can minimize its error so as to make it of little practical importance.

I received one of these inquiry sheets, of which this is a printed copy, is it not, Dr. Wilbur?

DR. WILBUR—No; that is an average rating from a study of a number of those sheets, representing the average opinion of a certain number of statisticians and sanitarians; merely a preliminary study for the purposes of this meeting.

DR. FULTON—I received such a sheet, asking me to give a rating to each of the titles. I went into it with care, as a man interested in the subject and as a specialist. After I was done I found my mind in exactly the condition in which Dr. Wilbur tells us the minds of so many medical men of the country are. After going over the entire list and reviewing it I found much in my own notes to criticise. Desiring to satisfy myself, I drew a second column, and put down an alternate series of ratings, and I found that in all important titles —the very definite diseases—I had no inclination to change the rating at all. There were a number of titles as to which I was inclined to very slightly increase or diminish my first rating. There were a considerable number of rather indefinite titles to which, on second consideration, I gave a rating very different from that which I had given at first. I was greatly interested in hearing Dr. Wilbur say that such was about the state of mind of other men.

I confess that I don't understand how Dr. Wilbur is going to make this mathematical basis of assignment available for clerks. I am inclined to believe that he will work it out in some practical way, although at present, as I say, I don't understand it. What I do understand very clearly, however, is that this work is going to be available for a successful revision of our classification every ten years. Such careful study year after year will enable us to take very definite and complete data to the next decennial revision. For this purpose I feel assured that the great practical utility is coming out of this part of the work; for the other I am hopeful, though I confess I don't understand it at present.

DR. G. T. SWARTS, Providence, R. I.—My feelings are precisely those stated by Dr. Fulton. When I commenced to express my opinion in figures in regard to the comparative valuation of these different diseases, I found myself somewhat in a quandary. After making my rating the question was whether it was satisfactory to me. I think the result will be that we will have to take the average, as was done in this acceptance of nomenclature classification. I am not satisfied with the classification at all. There are a great many subjects of importance left out, and a great many causes I don't agree with. Nevertheless, I am willing to let my personal opinion go, so that when the statistician finds some reports from one state and some from another, he will know that they are all classified from the same standpoint.

I am willing to submit my figures to what the Census Bureau finds is a proper average. Whether it will prove satisfactory or not, seems ambiguous to me at present, but surely, in the course of ten years, we ought to get to some point where we can understand the subject. It must be, however, thoroughly threshed out in the meanwhile.

Salt and Molasses for Cancer.—Salt as a cure for cancer is announced from India in the lay press, and an Australian physician has found molasses to be a sure cure. Salt and molasses have, at least, the valuable points of cheapness and simplicity.

THE PROPER PERINEAL PROSTATECTOMY INCISION.

NICHOLAS SENN, M.D., LL.D.

Professor of Surgery Rush Medical College; Surgeon-in-Chief St. Joseph's Hospital; Attending Surgeon Presbyterian Hospital.

CHICAGO.

Prostatectomy is the operation which is now attracting much attention among surgeons here and abroad. The more general adoption of this operation is comparatively of recent date. The necessity of the removal of the enlarged prostate gland, the most frequent cause of urinary obstruction in men advanced in years, has been recognized for a long time, but it was not until recently that the technic of the operation has been perfected to a degree that rendered it sufficiently safe to bring it within the scope of feasible and advisable surgical procedures. The literature on this subject is growing with astonishing rapidity. Individual and collective experiences are being published in the medical press at short intervals in bringing to the notice of the profession the different operative procedures which are being devised and practiced. The question as to the most feasible route by which to attach the diseased prostate has not been definitely settled. The suprapubic method has many weighty advocates, and for a time was deemed the easiest, most efficient and safest. The perineal route has, however, been given a more extended trial, and a very large experience appears to have decided in its favor. From an anatomic standpoint the perineal operation is certainly the most rational of the two, and will undoubtedly survive the test of time. The removal of the enlarged prostate does not always meet all the indications in the case operated on. Few cases come to the surgeon in which the bladder is intact in consequence of the mechanical obstruction or infection, hence in the majority of cases it becomes necessary to establish free drainage after the removal of the prostate for the purpose of initiating a successful treatment for the coexisting complications. In making the external incision the surgeon must therefore have in view the exposure of the prostate to sight and touch as freely as can be done with safety, and to provide for free drainage of the bladder and the perineal wound. The semilunar incision of Zuckerkandl and the triangular incision of Kocher accomplish neither of these objects to the fullest extent. I have given both of them a fair test and have become familiar with their shortcomings in securing the necessary room and the difficulty encountered in establishing free and efficient drainage for the bladder and perineal wound. The triangular incision of Kocher circumscribes a long wedge-shaped flap, the apex of which is liable to slough, and the curved incision of Zuckerkandl does not procure the necessary amount of room through which the prostate, in difficult cases, can be removed with the requisite degree of precision and safety, and both incisions leave a wound difficult to drain efficiently. The median incision so much praised by some surgeons is altogether inadequate in difficult cases. Every surgeon who has had an extensive experience in perineal prostatectomy has learned that not all enlarged prostates can be removed by enucleation. There are cases in which the diseased organ must be removed by morcellement. It is a rule in surgery which it is always well to bear in mind, and that is to operate as little as possible in the dark in important anatomic localities, and this rule applies with special force to perineal prostatectomy. In obese subjects and in cases of very large prostates it is often exceedingly difficult to bring the parts to be removed within

reach of the index finger. It is under these trying circumstances that the operator will appreciate the advantages of an incision that will expose the prostate freely and bring it within easy reach of the finger or the instruments required for its removal. Very little is gained by attempts to render the prostate more accessible by intravesical instrumental pressure, and such efforts are by no means always harmless. The danger from

Fig. 1.—Median perineal incision.

hemorrhage and accidental wounding of the peritoneum is reduced to a minimum by resorting to an incision that will expose the prostate in the freest possible manner to sight and touch. I have attempted to do this by combining the median incision with two lateral incisions representing in outline an inverted capital Y. The median incision is made in the usual way, laying bare the membranous portion of the urethra. The lateral in-

Fig. 2.—Zuckerkandl's incision.

cisions are carried from the lower angle of the median to a point half way between the anal margin and the tuberosity of the ischium, cutting through about the same structures as are involved in the lateral operation for stone in the bladder. The wound is next deepened largely by the use of blunt instruments and all hemorrhage arrested as it occurs, maintaining throughout the

Fig. 3.—Kocher's incision.

entire operation practically a bloodless field. This will give the operator an opportunity to recognize and identify the tissues as he proceeds with the dissection. In this comparatively bloodless way the rectum is detached until the membranous portion of the urethra and the lower segment of the prostate can be distinctly seen and felt in the apex of the deep triangular wound. By using narrow flat deep retractors the rectum is pushed backward and the wound margins are retracted laterally, thus exposing freely the parts concerned in the next step of the operation. I then proceed as follows: On a grooved staff which is now inserted into the bladder the membranous portion of the urethra is incised and the grooved director of Wheelhouse inserted into the bladder. Withdrawing the staff and using the director as

Fig. 4.—Author's incision.

a guide the prostatic part of the urethra is dilated with the left index finger which, after it enters the bladder, serves as a blunt hook with which the prostate is drawn gently downward and forward into the wound. The capsule of the gland is next incised transversely and with the opposite index finger enucleation of the left lobe is commenced. This part of the operation is usually easy,

Fig. 5.—Prostate and membranous portion of urethra seen on retraction of wound margins.

sometimes difficult and not infrequently impossible. Recklessness and undue violence are to be carefully

Fig. 6.—Operation completed.

avoided. Enucleation is often facilitated by grasping the lower part of the prostate with my bullet forceps or some other grasping instrument on which traction is made during the process of enucleation. I seldom attempt to remove the prostate in its entirety. Occasionally this can be done, but usually it will be found much easier to remove only one lobe at a time. After the

removal of the left lobe the right index finger is inserted into the bladder and the right lobe enucleated with the left. If it is found impracticable to remove the prostate by enucleation morcellement must be resorted to. The finger in the bladder is almost indispensable in operating by this method. With it the parts are brought within easier reach and it serves at the same time as a valuable guide for the use of the cutting and traction instruments. With grasping forceps portions of the gland are seized, when the necessary traction is made by an assistant while the surgeon does the cutting with blunt-pointed scissors well curved on the flat. Complete prostatectomy in such cases is not necessary, but enough tissue must be removed to insure a free outlet for the urine and to guard against a recurrence of obstruction from the same cause. I am decidedly in favor of a preliminary cystotomy in performing perineal prostatectomy, as it greatly facilitates the removal of the gland by enucleation or morcellement, and in the majority of cases it becomes a necessity for the treatment of complicating affections of the bladder. It is preferable to incise the urethra and take advantage of such an opening into the bladder during the operation than to tear it accidentally, as is so often done when operators undertake a perineal prostatectomy without a preliminary cystotomy. I invariably drain the bladder by inserting a soft rubber drain with two oval fenestra near the vesical end. The drain is fastened in the lower angle of one of the lateral incisions with a suture which includes the outer margin of the wound. The perineal wound is drained with a strip of iodoform gauze which is brought out on the side of the rubber drain. The balance of the incision is sutured. The bladder is kept practically empty by siphonage by connecting the perineal drain with another piece of rubber tubing, making the connection with a glass tube. Through this rubber drain the bladder can be washed out daily with appropriate antiseptic solutions. The iodoform gauze drain should remain for at least five or six days, as its presence in the wound is of the greatest value in preventing infection by leakage of septic urine. The bladder drainage must be continued until the condition of the urine is such as to warrant suspension of intravesical medication. In regard to the indications for prostatectomy history will repeat itself. Every new surgical procedure has had its enthusiastic advocates who championed extreme views and who would recognize no exceptions, and who followed a routine practice. I will refer only to a few operations of recent date that have had such a history. It is not long since thousands of ovaries were sacrificed under the belief that the anticipated climacteric period would correct all kinds of obscure nervous affections until sad experience proved the contrary. Craniectomy for microcephalus had a short but exciting career. It is impossible to estimate the number of healthy appendices that have been removed by surgeons who rely on pain in the right iliac fossa as a conclusive evidence of a diseased vermiform appendix, and resort to the knife as the only remedy. Castration for enlarged prostate has unsexed hundreds of men without yielding them an equivalent in relief for the loss sustained. Gall-bladder surgery has now a few extremists who affirm that it should be dealt with in the same medical manner as the appendix when it is the seat of disease. Instances could be multiplied, but the early history of the operations mentioned will suffice that new operations are very likely to be abused when first placed on trial, and prostatectomy can not escape a similar fate. It is impossible at the present time, so early in the history of this operation, to formulate the exact indications. The size of the prostate is no criterion to go by in deciding on the propriety or necessity of an operation as a large prostate may cause less disturbance of function of the bladder than one only moderately enlarged. The degree of obstruction depends more on the location of the enlargement and the effect of pressure on the urethra than the size of the swelling. Every prudent surgeon would hesitate to recommend a prostatectomy in men 70 to 80 years of age, the subjects of extensive atheromatous degeneration of the arteries or of organic disease of any of the important viscera. Systematic aseptic catheterization will not be displaced entirely by prostatectomy, and it will continue to be a most valuable resource in the future, as it has been in the past, in the treatment of hypertrophy of the prostate, more particularly in men advanced in years the subjects of degenerative diseases which in themselves would contraindicate the performance of any operation of importance except as an immediate life-saving procedure. It will be with this as with any other operative procedure that the best results will be obtained by surgeons who search as carefully for the negative as for the positive indications for the operation. The present technic of prostatectomy will be greatly improved, and its legitimate range of usefulness will be widened with increasing clinical experience and with a more definite knowledge of the etiology and pathology of senile hypertrophy of this gland.

THE ESSENTIAL PRINCIPLES OF INFANT FEEDING AND THE MODERN METHODS OF APPLYING THEM.

THOMAS MORGAN ROTCH, A.B., M.D.
Professor of Pediatrics, Harvard University.
BOSTON.

(Concluded from p. 354.)

MILK LABORATORIES.

The next question is where and in what way the modification of the milk is to be carried out. This problem has been to a great extent solved since the establishment of what are termed milk laboratories. Up to the present time the milk laboratories have been under the control of one company called The Waker-Gordon Laboratory Company, which was established in Boston in 1891 by Mr. G. E. Gordon, Mr. Geo. H. Walker and Mr. J. H. Waterhouse. These milk laboratories are intended to take the same position toward the modification of milk that apothecary shops have to drugs. That is, directions for substitute feeding can be sent in the form of a prescription to the milk laboratory, and should only be dispensed and sold under the direction of a physician. It is well that this should be clearly understood, as it places the milk laboratories in the strong position which they have up to this time held by being endorsed by the physician and by giving the public to understand that they are merely a means by which physicians can accurately carry out their ideas as to the substitute feeding of their patients.

Emanating from Boston, laboratories have been established in this country in New York, Philadelphia, Chicago, Baltimore, Buffalo, Cincinnati, Cleveland, Grand Rapids, Pittsburg, St. Louis and Washington; in Canada in Montreal, Ottawa and Toronto, and in England in London. In connection with these laboratories are farms belonging to the Walker-Gordon Company and especially equipped for supplying the best milk for substitute feeding. The farms and the laboratories

in this way are kept in close touch, and the important matter of a fresh milk supply is thus dealt with and carried as nearly to perfection as is possible under the existing conditions.

The materials which are needed to carry out the physician's prescriptions in these laboratories are:

1. Creams of different but definite fat percentages, obtained either by gravity or by centrifugal separation.
2. Fat-free milk, which is used to increase the percentage of proteids in the substitute food beyond that contributed by the cream.
3. Milk sugar to raise the percentage of the sugar above the amount contributed by the cream and the fat-free milk.
4. Lime-water to increase the alkalinity.
5. Boiled or distilled water as a diluent.
6. Cereal waters and jellies, usually of barley or oat meal, which in certain cases, if the physician prescribes it, can be used as a diluent, or, in the latter part of the first year, to provide the necessary element of starch.
7. Special apparatus for pasteurizing, sterilizing or heating the mixtures at any required temperature.

The milk supply from the farms connected with these laboratories is treated with such care that it shows a remarkably low bacterial content, so that it often can be transported for long distances without the necessity of pasteurization, sterilization or the addition of preservatives.

These laboratories established in the interest of substitute feeding are, then, simply places where milk, which has been obtained under the best conditions, is supplied, where physicians can send their prescriptions calling for any percentage of fat, sugar, proteids, alkalinity or anything else which is desirable, and where these prescriptions can be put up cleanly and accurately.

The following is the sample prescription blank which is at present used in the Walker-Gordon laboratories, and a sample prescription:

THE WALKER GORDON LABORATORY.

		Per cent.
℞.	Fat	3.50
	Milk sugar	6.50
	Whey proteids	0.50
	Caseinogen	0.25
	Lime water	5.00

Heat at 155 F. Number of feedings, 8. Amount at each feeding, 4 oz. Ordered for.....

Address..... Date.....190..

....., M.D.

Physicians who do not wish to subdivide the proteids may erase the words "whey" and "caseinogen," and simply write for the percentage of the total proteids desired. They may also write for as many ounces of cereal water or jelly in each tube as may be desired, the cereal being added in place of the water used in making the modification, so that the percentage of fat, sugar, and proteids are not materially altered.

By examining the prescription it will be seen that the substitute food is written for simply in percentages, and that by this method the physician does not have to calculate the various amounts of cream or separated milk or sugar or anything else which he may wish to have introduced into the food, these being calculated at the laboratory for him. The great advantage in using the laboratory methods for preparing a substitute food is not only the relative greater certainty of the purity and the freshness of the milk supply, but also that the percentages of the different elements of the milk and cream being known each day, the calculations for any especial percentages are more likely to be correct. We must not, however, expect, in the present state of our knowledge, when a prescription of certain percentages is written for, that these percentages in the resulting mixture will be absolutely correct. Practically, however, they have been shown to be reasonably accurate, and necessarily are more accurate than when the mixtures are prepared by other methods or in the patient's home. The following analyses of laboratory mixtures were made by Dr. Edsall of Philadelphia, who is well known as a skilled chemist, as well as a practical worker in the care of children.

The mixtures were calculated at and put up in the Walker-Gordon Milk Laboratory in Philadelphia.

TABLE 9.

Percentages as calculated by the laboratory.		Percentages in the same mixtures as estimated by chemical analysis by Dr. Edsall.	
Fat.	Proteids.	Fat.	Proteids.
1.5	.75	1.3	.822

2.5	1.50	2.6	1.2881
2.5	1.50	2.6	1.4098
2.5	1.50	2.2	1.143
2.5	1.50	2.6	1.3
3.5	1.75	3.55	1.6355
3.5	1.75	3.3	1.6335
3.5	1.75	3.3	1.544
3.5	1.75	3.28	2.2151
4.0	1.75	3.9	2.1794
4.0	1.75	4.2	1.544
4.0	1.75	3.3	1.536
4.0	1.75	3.8	1.7049
4.0	1.75	3.9	1.557
4.0	1.75	3.7	1.562

After the prescription has been made up at the laboratory by the laboratory modifying clerks the number of tubes required for the special substitute feeding, each tube containing the amount which the physician wishes the infant to have at one feeding, are placed in an ice box especially adapted for the purpose of transportation to the patient's home. On the following day, when the fresh supply is brought, the ice box and tubes of the previous day are taken back to the laboratory. The greatest care is taken not only to have practically sterile tubes go out from the laboratory, but when the empty tubes are returned, to thoroughly sterilize them before they are brought into the modifying room.

Although an accurate composition of a substitute food can be better obtained in a laboratory than anywhere else, yet there arise cases in which a laboratory can not be conveniently reached, or in which for some special reason, the physician or the patient prefers to make the substitute food at home. We must remember, however, that many children are fed in a satisfactory manner from laboratories at a great distance from their homes. Thus, before the establishment of the Chicago laboratory the New York laboratory supplied a number of cases in Chicago. In the same way the Boston laboratories have sent, even during the hot weather, food to different parts of Maine, and the southern states have been supplied from the Washington laboratory. It is quite common for the laboratories to supply food for long ocean voyages, and the laboratory methods have been found to be remarkably successful in this part of the work. As to the relative expense incurred in

feeding from the laboratory, or from mixing the food at home, there is not a very great deal of difference, especially if good milks and creams of different percentages are provided for what is usually known as home modification.

The general principles for modifying milk are the same whether the milk is modified in the laboratory with carefully protected milk, and by skilled hands, or in the homes from whatever milk the individual is able to obtain and by hands as skilled as possible in the special household. The physician must, therefore, in making use of home modification adapt his methods as nearly as possible to those which are employed in the laboratories. This implies the careful choosing of a herd of cows, as clean and fresh milk as possible, and a reasonable certainty as to the strength of the cream used.

HOME MODIFICATION.

The chief difficulty associated with the home modification of milk lies in the uncertainty in regard to the percentages of the materials with which we are working. If creams of guaranteed strength can be purchased from the laboratories or similar places, a home modification may be made with a considerable degree of accuracy. On the other hand, if we are dependent on the use of gravity cream obtained from milk of uncertain composition, the strength of the cream can only be approximately estimated. We may, however, assume that a quart of milk which contains 4 per cent. of fat to start with, and which has been allowed to stand for a varying number of hours, will yield approximately the following percentages of fat in the different layers of milk:

TABLE 10.

Cream, 10 per cent. in the upper	8 ounces after 6 hours.
Cream, 10 per cent. in the upper	11 ounces after 8 to 12 hours.
Cream, 12 per cent. in the upper	8 ounces after 8 hours.
Cream, 16 per cent. in the upper	6 ounces after 8 hours.
Cream, 20 per cent. in the upper	4 ounces after 4 to 6 hours.

Milk containing practically no fat, or, as it is called, "fat-free milk," can be obtained from the lowest eight ounces of a quart of milk which has been set for eight or more hours. The other materials used in modification, that is, lime-water, distilled or boiled water and milk-sugar, can be easily provided.

Having on hand the materials for the modification, the next point consists in making the calculation for the different amounts of each material to be used in order to obtain the desired percentages of fat, sugar and proteids in the resulting mixture. These calculations may be made either by means of formulæ such as have been published by Taylor, Baner and Westcott, or they may be obtained by the feeding-card presently to be described.

If formulæ are to be used, it is essential that we should adopt a standard for the analysis of the different materials used, and the standard which is now most generally accepted may be stated as follows:

TABLE 11.

	Fats.	Sugar.	Proteids.
Fat-free milk	Trace.	4.60	3.60
Whey	Trace.	4.79	1.00
Whole milk	4	4.50	3.50
Eight per cent. cream	8	4.40	3.40
Ten per cent. cream	10	4.30	3.35
Twelve per cent. cream	12	4.20	3.30
Sixteen per cent. cream	16	4.05	3.20
Twenty per cent. cream	20	3.90	3.10

FORMULÆ FOR MILK MODIFICATION.

The most complete series of formulæ for the modification of milk which has yet been published is that of Dr. Thompson S. Westcott of Philadelphia, which was published in the International Clinics, October, 1901. Taking the previous formulæ of Taylor and those of Baner, he has worked out mathematical formulæ which are of universal application, and has established the principles of percentage modification on a truly scientific basis.

The formulæ which he gives are rather too elaborate to be given in this paper. For the sake of completeness, however, it may be well to give the formulæ for obtaining the desired combinations based upon the use of creams and fat-free milk. The use of creams and fat-free milk, instead of the use of cream and whole milk, simplifies very greatly the work of computation, as may readily be seen by referring to Westcott's paper. Moreover, it is a more economical method, as the fat-free milk may be obtained from the same quart from which the cream is separated. The formulæ may briefly be expressed as follows:

TABLE 12.

F.=prescribed percentage of fat.
S.=prescribed percentage of sugar.
P.=prescribed percentage of proteids.
C.=total quantity of cream in ounces.
M.=total quantity of milk in ounces.
W.=total quantity of water in ounces.
L.=total quantity of dry milk sugar in ounces.
Q.=total quantity of mixture.
a =known percentage of fat in cream.
a′=known percentage of fat in milk.
b =known percentage of proteids in cream.
b′=known percentage of proteids in milk.

The amount of cream to be used is;

$$\text{Cream (C)} = \frac{QF}{a}$$

The amount of fat-free milk to be used is:

$$\text{Fat-free milk (M)} = \frac{QP - bC}{b'}$$

The amount of sugar is:

$$\text{Sugar (L)} = \frac{QS - 4.50\ (M+C)}{100}$$

which gives the amount of sugar in ounces.
The amount of water to be added is:

$$\text{Water (W)} = Q - (C + M).$$

A comparatively unimportant error arises in the calculation of the sugar by the assumption that the percentage of sugar in the mixture of fat-free milk and cream is the same as that in whole milk, that is, 4.50 per cent.

To many physicians, however, the use of a formula is more or less inconvenient, both because of the time required to make the computation and because of the difficulty which some minds experience in using algebraic formulæ. In order to simplify the work of calculation, a very practical and simple method has been devised by Dr. Maynard Ladd, a member of the pediatric department at Harvard University.

DR. LADD'S CARD FOR HOME MODIFICATION.

This method consists of a card small enough to be carried conveniently in the pocket and on which are given thirty different combinations of fat, sugar and total proteids with the amounts in ounces of cream, fat-free milk, lime-water, boiled water and milk-sugar to be used in obtaining these combinations.

By referring to this card it is seen that it is so arranged that a physician may exercise a choice in the percentage of cream to be used, and can see at a glance what combinations are possible and what combinations impossible with the creams of different strengths. The calculations are made for twenty-ounce mixtures. For twenty-five ounce mixtures the amount of each ingredient is multiplied by 1¼. For a thirty-five ounce mixture the amount of each ingredient is multiplied by 1¾ and for a forty-ounce mixture the amount of each ingredient is multiplied by 2. The percentage

of lime-water may be increased at will, by remembering that each additional ounce in a twenty-ounce mixture increases the alkalinity 5 per cent., and the amount of lime-water added beyond what is given in the total amount must be subtracted from the amount of water used as a diluent. For accuracy the milk-sugar should be dissolved in a portion of the water, and then enough water added to make the amount called for. The amount of sugar required is expressed in measures; the measure is a small tin dipper obtained at the milk laboratory, and holds just 3⅜ drams, which is approximately a level tablespoonful.

TABLE 13.

For 25-oz. mixtures multiply amount of each ingredient by 1¼
For 30-oz. mixtures multiply amount of each ingredient by 1½
For 35-oz. mixtures multiply amount of each ingredient by 1¾
For 40-oz. mixtures multiply amount of each ingredient by 2
For 45-oz. mixtures multiply amount of each ingredient by 2¼

* Combination impossible with strength of cream indicated.

The following is an example of the way in which this card may be used: Suppose that it is desired to give a baby a mixture calling for a 4 per cent. fat, 7 per cent. sugar, 1.25 per cent. proteids, 5 per cent. alkalinity, and five feedings of eight ounces. By referring to the table it will be seen that this corresponds to formula 24. Looking into the cream column we see that it is impossible to obtain this combination with a cream of 10 per cent. fat, but it may be obtained with a cream of 12 per cent. fat. As forty ounces of milk are to be given the baby in the course of twenty-four hours, it will be necessary to double the quantity of each ingredient, and the calculation is readily made as follows:

TABLE 14.

12 per cent. cream	6¾ ounces	x 2 = 13½ ounces.
Fat free milk	¾ "	x 2 = 1½ "
Lime water	1 "	x 2 = 2 "
Boiled water	11½ "	x 2 = 23 "
Milk sugar	2½ measures	x 2 = 5 measures.

The mother is then told how to obtain a cream of 12 per cent. strength, following the rules given above. By referring to the table of creams it will be seen that a cream of 12 per cent. may be obtained from the upper eight ounces of a quart of milk which has been allowed to set in a cool place for eight hours. The mother may be directed either to siphon off this cream, or to remove it by means of a dipper, or she may pour off the top eight ounces into a graduate. Two quarts of milk will be necessary to obtain the amount of cream necessary for this modification. The fat-free milk is obtained from the lowest eight ounces of the quart from which the cream has been removed. The ingredients are mixed and five nursing bottles are then filled, each with five ounces of milk, stoppered with cotton, and then pasteurized or not, as the physician chooses to direct.

Whey-cream mixtures may be obtained by using whey as a diluent, in place of the boiled water, preferably in the combinations containing low proteid percentages. Each two ounces of whey replacing an equal quantity of water in a twenty-ounce mixture will raise the whey-proteids, 0.10 per cent., and will increase the sugar percentage 0.50. The total sugar percentage is therefore, the amount contributed by the cream and fat-free milk, which is indicated in the last column of table 13, plus that of the whey. The amount of dry sugar which must be added to make the desired final sugar percentage can be easily calculated by referring to the following table.

TABLE 15.

	Per cent. of sugar.
One measure of dry lactose in a 20-oz. mixture gives	2.00
One-half measure of dry lactose in a 20-oz. mixture gives	1.00
One-quarter measure of dry lactose in a 20-oz. mixture gives	.50

(One measure is approximately one level tablespoonful.)

Example: If in formula 21 of Dr. Ladd's card, fourteen ounces of whey are added in place of the same quantity of water, the whey-proteids are increased 0.70 per cent., making total proteids of 1.30 per cent. The sugar contributed by the cream is 0.78; that by the whey 3.50—making a total of 4.28. The desired percentage of sugar is 6, therefore the balance of 1.72 per cent. may be obtained by adding a little short of the measure of sugar.

Whey should be made of fresh fat-free milk and liquid rennet, and should be heated to 150 F. (65 C.) to destroy the rennin enzyme before it is added to the cream mixture. One quart of fat-free milk will yield about twenty-four ounces of whey.

EDSALL'S COMPARATIVE ANALYSES.

Dr. Edsall of Philadelphia has carefully estimated the percentages of the fat and proteids where the mixtures have been prepared by means of formulæ in the hospital, by trained nurses, at the out-patient department of the University of Pennsylvania, and by a number of physicians. The results under these conditions were not so good as when the modifications were done in the laboratory. Dr. Edsall has also carefully estimated mixtures that have been put up according to the figures on Dr. Ladd's card, and has found that the results were very accurate, approaching closely those of the laboratory modifications. It would seem, therefore, that the laboratory modifications are best if they can be obtained, but that if home modification is to be used, the

method suggested by Dr. Ladd will probably give the most accurate and successful results.

GENERAL PRINCIPLES OF PERCENTAGE FEEDING.

Having described the general principles of modifying milk and explained the various methods whether by laboratory modification or home modification by special formulæ, or by the feeding card, it may be well for me to say a few words about the general principles of percentage feeding.

This system of percentage feeding has been so much more elaborated in America than elsewhere that it is often spoken of as the American method. It simply means that each individual infant must be studied by itself; that its special idiosyncrasies must be allowed for, and that its food should be adapted to its age, weight and other conditions, whether normal or abnormal. This seems to be the most rational manner of approaching the subject, and, although there are many factors of the problem which have not yet been entirely solved, yet the principle having been determined, greater accuracy will necessarily follow the continuous investigation of the subject.

So far as the materials of the food are concerned, we conclude that it is practical to use cow's milk for a substitute food, and that the milk should be from cows of hardy breeds, such as Durham, Devon, Ayrshire and Holstein. These grades are noted for their constitutional vigor, adaptability to acclimatization, notable ability to raise their young, freedom from intense inbreeding, a distinctly emulsified fat in the milk, and a preponderance in the fats of the fixed over the volatile glycerids.

In regard to the heating of the milk, the temperature should vary according to the especial conditions. Where whey is used to obtain a definite percentage of the whey-proteids, a temperature sufficient to kill the rennin enzyme, used in obtaining the whey, and not so high as to coagulate the whey-proteids, should be employed. An intermediate temperature of 155 F. (68.3 C.) meets this condition.

In hot weather, and when the distance for transportation is great, also in diarrheal diseases, it is sometimes found desirable to heat the milk to a much higher temperature, such as 212 F. (100 C.). It may be said, however, that with the present care which is taken to preserve the milk used for laboratory purposes, it has been found that either sterilization or pasteurization is often unnecessary.

In regard to the reaction, a slightly alkaline reaction seems to accomplish the most favorable results. The lime-water does not appear in itself to interfere with the infant's digestion. Care should be taken, however, when a large percentage of lime-water is added to the milk, such as 15 or 20 per cent., that it should be added just before the milk is given if it is decided to heat the food at a high temperature, such as 212 F. (100 C.). This precaution is taken because if the lime-water and milk-sugar are heated together at a high temperature a reaction takes place seemingly between the lime-water and the milk-sugar, with a resulting discoloration of the milk.

In regard to the percentages which should be given under different conditions, you may perhaps wish to know what my custom has been. We may divide all feeding cases into two broad classes, one in which the infant is normal for its age, both in digestion and nutrition, and a second class in which there is some disturbance in the digestion and nutrition of the infant.

The feeding in the first class of cases, in which the infant is normal at birth, presents very few difficulties, as a rule, when the case is intelligently managed. It is necessary, however, to bear in mind that even a normal infant can not be started at once on a modified milk, corresponding in its percentages to human milk. It is a cardinal principle in the feeding of both healthy and sick infants, to start with weak milks and gradually to strengthen one element after another until the child is taking a milk of full strength. The rapidity with which this can be accomplished will depend largely on the idiosyncrasy of the infant. In some cases we are surprised at the strength of the food which the child can digest, in other cases the progress from a very weak to a very strong milk can only be made slowly and with caution.

In a general way it has been my experience that the fats should be from 1.5 to 2 per cent. during the first week, and from 2 to 2.5 per cent. in the second and third weeks. By the end of the month the infant should be taking from 3 to 3.5 per cent. of fat. Four per cent. of fat should be reached anywhere from the sixth week to the sixth month.

The sugar percentage can be pushed up rapidly, beginning with 5 per cent., and by the end of a month in most cases we can give 7 per cent. It is rarely necessary to go higher.

The proteids present the greatest difficulty, and as a rule must be increased very gradually, beginning with a total percentage as low as 0.50, and preferably in young infants using the splitting the proteid so as to give 0.25 whey-proteids and 0.25 caseinogen. This will suffice for the first week or two. At the end of a month the infant is usually taking 1 per cent.; at the end of the second or third month 1.25 to 1.50 per cent., and from the fourth to the fifth month about 2.00 per cent. The full total proteid of 3.50 is rarely tolerated before the tenth or twelfth month. At any time when necessary or desired the various combinations of the split-proteid can be used instead of the undivided proteid.

Table 16 summarizes what has just been said, giving the formulæ, according to the feeding-card on which the average healthy baby may be started.

Table 16.

Premature	No. 1 or 2
2-4 weeks	No. 5, 8, 9 or 11
1-2 months	No. 12 or 13
2-4 months	No. 19 or 20
4-6 months	No. 24 or 25
6-8 months	No. 26 or 27
8-9 months	No 28

Rules for Feeding.

Day feedings begin at 6 a. m., and end at 10 p. m.

Age of Infant.	Intervals in Hours.	No. of Feedings in 24 Hours.	No. of Night Feedings.	Amount ozs. at Each Feeding.	Total Amount of ozs. in 24 Hours.
1 week ..	2	10	1	1	10
2 weeks ..	2	10	1	1½	15
4 weeks ..	2	9	1	2½	22½
6 weeks ..	2½	8	1	3	24
8 weeks ..	2½	8	1	3¼	26
3 months .	2½	7	0	4	28
4 months .	2½	7	0	4½	31½
5 months .	3	6	0	5½	33
6 months .	3	6	0	5¾	34½
7 months .	3	6	0	6¼	37½
8 months .	3	6	0	7	42
9 months .	3	6	0	7	42
10 months	3	5	0	8½	42½
11 months	3	5	0	8¾	43¾
12 months	3	5	0	9	45

While these changes in the percentage composition of the milk are being made, it is equally important to regu-

late the number of feedings, the intervals between the feedings and the quantity at each feeding. The manner in which this is done is seen in Table 17.

TABLE 17.
RULES FOR FEEDING.
Day feedings begin at 6 a. m., and end at 10 p. m.

Age of Infant.	Intervals in Hours.	No. of Feedings in 24 Hours.	No. of Night Feedings.	Amount ozs. at Each Feeding.	Total Amount of ozs. in 24 Hours.

4 months .	2½	7	0	4½	31½
5 months .	3	6	0	5½	33
6 months .	3	6	0	5¾	34½
7 months .	3	6	0	6¼	37½
8 months .	3	6	0	7	42
9 months .	3	6	0	7	42
10 months	3	5	0	8½	42½
11 months	3	5	0	8¾	43¾
12 months	3	5	0	9	45

The feeding of infants with weak digestions can not be so easily managed. At times it is impossible to say what element of the food is causing the trouble, or it may be that all three elements, fat, sugar and proteids, are at fault, or that the appropriate combinations of percentages has not been employed. The secret of successful management of these cases is to provide rest for the stomach. This can best be accomplished by putting the infant, irrespective of its age, on a milk easily within its digestive power, perhaps giving it no higher than 1.5 to 2 per cent. of fat, 5.00 per cent. of sugar, and 0.50 per cent. of proteid.

The infant is to be kept on this mixture until the discomfort of indigestion has passed away, and then we should begin gradually to increase one element after another, until it is taking a food appropriate to its age. The great mistake made by most physicians is their aversion to making so radical a change as that just indicated. They try to decrease the strength of the milk working downwards until a digestible mixture is obtained, whereas they should begin at once at the bottom and work upward.

The majority of cases of difficult digestion are due to the caseinogen, and it is for this reason that I have found the use of the whey-cream mixtures of the greatest value. I am accustomed to use mixtures giving only 0.25 per cent. of caseinogen and rapidly to run the whey-proteids up to 0.90 per cent. (the highest that can be given); then keeping the whey-proteids at 0.90 per cent., I advance the caseinogen first to 0.50 per cent., then to 0.75 per cent., then to 1.00 per cent. The next change is to a total proteid of 1.50 per cent. and then to 2.00 per cent.

Very rarely, in addition to careful modification, partial or complete peptonization may have to be resorted to, but such cases seldom arise, if we diligently and intelligently carry out the essential principles underlying the adaption of cow's milk to an infant.

Finally, let me reiterate what I have said before in other words. Sick infants can not be fed by rule of thumb. We can only lay down the general principles governing the milk supply, the subsequent modification of the milk and finally its adaption to the particular child. Each sick infant is a study by itself. The most successful feeder of infants will be the man who has at his command the many resources embodied in our modern methods of percentage feeding, and who can appreciate the individual needs of the especial infant.

CLIPPINGS FROM LAY EXCHANGES.

FEARFUL AND WONDERFUL NAME.

"'Coccus babyllus polymohpus lissac' is the name given to the hydrophobia microbe by its discoverer" . . . *Binghamton* (N. Y.) *Herald*, June 29.

ANTIPHENACETINE POULTICE.

"Last night Jeffries defied his trainer and doctor by pulling off the antiphenacetine poultice that had been applied twenty-four hours before."—*Chicago Tribune*, July 27, 1903.

ARE "ECLECTIC" AND "EPILECTIC" SYNONYMOUS?

"The epileptic staff of the county hospital elected officers," . . . *Chicago Record-Herald*, July 19, 1903; "A meeting of the epileptic staff . . . was held . . ," *Chicago Chronicle*, July 20, 1903.

CARDIECTOMY PROPOSED.

A London despatch to the *New York Herald*, and published in the *Ithaca* (N. Y.) *News* of June 29, gives the details of a case of stab-wound of the heart. The surgeon "at first thought the heart itself would have to be removed, but on washing away the blood clots and raising it a little the puncture was found."

INGESTED INTESTINE.

"Dr. —— came to Newkirk about two years ago. . . . . A few months ago a baby was born, elating the young physician and spurring him on to renewed effort. About two weeks ago the doctor incurred appendicitis. . . . The operation revealed the fact that the intestine had been eaten, a dangerous symptom."—*Newkirk* (O. T.) *Journal*, Dec. 25, 1902.

MAY BE CYANOSIS.

"His Disease Puzzles Surgeons—Deaf Mute's Body Turns Dark and He Is Unconscious—May Be Cyanosis.—The peculiar symptoms of the illness from which —— is suffering puzzle the surgeons . . . From chest to head his body is discolored and the physicians are unable to explain the cause. . . . The surgeons finally concluded that he was suffering from cyanosis, which is a diseased condition of the circulation, causing a livid bluish color of the skin."—*New York Tribune*, Aug. 5, 1903.

EVERLASTING ANESTHESIA.

A fervid obituary notice which appeared in the *Somerset* (Ky.) *Journal*, of Jan. 13, 1903, contains the following literary gems:

"How inconceivably cold is the grave and the state of death! To-day in this winter atmosphere, through the drifting snow, into the frozen ground they are burying our recent familiar friend and fellow, Dr. ——, yet his once sensative nerves are so benumbed by the chill of death that he feels not the frigid environment.

"When I, with his employer and friend, ——, saw him the other day (6th inst.), and I took the emaciated hand and met the weak but lucid eye, life's near extinction was apparent, but I did not realize then that in six short hours he would be brought fully under the everlasting anesthesia."

Alcohol Applications in Pleurisy, Peritonitis and Arthritis.—Local application of alcohol has proved effective in curing cases of this kind in the experience of Dr. Ssaweljew of Dorpat, as he reports in the *Allg. Med. Ct.-Ztg.*, lxxii, p. 257. He keeps the part wet with a bandage saturated with alcohol and reports unusually rapid recoveries. In case the patient wishes to be up he applies the alcohol on cotton covered with perforated parchment paper, the whole held in place by a suspending bandage. The alcohol is poured through a glass funnel into the perforations as needed. He does not attempt to explain the mechanism of its action, which has been theorized on by many writers, but contents himself with detailing the results of the measure, which he thinks he is the first to apply in pleurisy.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue . . . . . Chicago, Ill.

Cable Address . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

SATURDAY, AUGUST 15, 1903.

Owing to the amount of space given to the educational matter in this issue, many of the regular departments are abbreviated and some are omitted.

MEDICAL EDUCATION IN THE UNITED STATES.

This week's issue of THE JOURNAL is the third annual educational number, and contains the statistics regarding medical education in the United States covering the year ending June 30, 1903. We believe that the statistics presented in this number, and for the two years preceding, are absolutely correct. It will not be out of place to say that until THE JOURNAL, four years ago, undertook to annually gather the information, there was no way of knowing even the number of medical colleges, much less the number of students in, and graduates from, these colleges, aside from the information furnished by the publications of the Commissioner of Education, which are usually a year behind. There were plenty of vague guesses and wild statements made regarding the number of colleges, students and graduates, just as to-day the same kind of statements are made regarding the number of physicians in the United States, which is an unknown quantity.

The average reader, making a casual glance at the statistical and other information presented, will possibly imagine that it was a simple matter to obtain it. He will naturally suppose that a letter to the dean or secretary of a college would bring the information desired. We are sorry to say, however, that this is not correct. Three months have been covered in this work, and yet even as we go to press it has been impossible to get a reply from anyone connected with two of the colleges listed. In a number of instances three or four letters to the dean or secretary or president would have to be supplemented by letters to individual members of the faculties or even to outsiders, before the information desired could be had. This criticism, we are happy to say, applies only to less than twenty institutions, the officers connected with the other colleges replying promptly to our requests for information. We extend thanks to all who aided us in gathering these statistics.

Medical Students in the United States.—The number of medical students in the United States for the year ending June 30, 1903, was 27,615. Of this number 24,930 were at the regular schools, 1,498 at the homeopathic, 848 at the eclectic and 339 at the physio-medical and nondescript schools. There was an increase in the attendance at the regular schools of 52 over last year, and an increase of 1,094 over the year previous—1901. In the homeopathic schools there was a decrease of 119 below that of 1902, and a decrease of 185 since 1901. The eclectic, however, seem to have increased in the number registered. This past year there were 848 registered, against 765 of the preceding year, and 664 in 1901, showing an increase of 83 over 1902, and 184 over 1901. Those in attendance at the physio-medical and nondescript schools numbered 339, an increase of 98 over last year, and 115 over 1901. We give below a comparative table:

TABLE OF MEDICAL COLLEGE ATTENDANCE.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880*....	9,776	1,220	830	...	11,826
1890*....	13,521	1,164	719	...	15,404
1900*....	22,710	1,909	552	...	25,171
1901.....	23,846	1,683	664	224	26,417
1902.....	24,878	1,617	765	241	27,501
1903.....	24,930	1,498	848	339	27,615

Number of Graduates.—The total number of graduates in medicine for the year ending June 30, 1903, was 5,698, an increase of 699 over the preceding year. By referring to the table given below, it will be noticed, however, that this is an increase of only 254 over the number of graduates for the year ending June 30, 1901. As we stated last year, the decrease in the number of graduates in 1902 is assigned to the increased length of course of study and increased requirements by state boards. As we stated then, the decrease might be considered as only temporary, and this is proving to be true. However, the normal condition as regards the number of graduates to the number of students registered has probably not yet been reached, for a very large number of the medical schools adopted the four years' course during the last three years:

TABLE OF MEDICAL COLLEGE GRADUATES.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880*....	2,673	380	188	..	3,241
1890*....	3,853	380	221	..	4,454
1900*....	4,715	413	86	..	5,214
1901.....	4,879	387	148	30	5,444
1902.....	4,498	336	138	27	4,999
1903.....	5,088	420	149	41	5,698

Number of Colleges.—The number of medical colleges in the United States which grant the degree of M.D. is 154. Of these 121 are regular, 19 homeopathic, 10 eclectic, 3 physio-medical, and 1, the National Medical College of Chicago, nondescript, this institution advertising to teach not only according to the tenets of the four "schools" mentioned, but also osteopathy. In addition to the above, there are three schools which give instruction in the first two years' work. In other words, there are 157 institutions devoted to teaching medicine in the United States.

Our report for last year showed that there were at that time 156 medical colleges which conferred the degree of M.D. This, however, included the West Coast Medical College of San Francisco, which we found, when too late, should not have been included. Thus there has been a decrease of one college this year. An analysis of the report of medical colleges, given on pp. 436 to 449, with

* These statistics were obtained from the report of the Commissioner of Education.

the similar report of last year, shows that three new colleges have been started and four have gone out of existence by consolidation or otherwise.

We give below the number of medical schools, and include for comparison the same statistics for the years 1880, 1890 and 1900:

Comparative Table of Medical Colleges.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880*....	72	12	6	..	90
1890*....	93	14	9	..	116
1900*....	121	22	8	..	151
1901.....	124	21	10	4	159
1902.....	121	20	10	4	155
1903.....	121	19	10	4	154

Colleges Located in Small Towns.—It is acknowledged by all who have given thought to the subject that a town of less than 50,000 inhabitants can not, except under unusual circumstances, supply the clinical advantages that third and fourth-year students require. Yet the fact is there are thirty medical colleges located in towns of less than 50,000 that confer the degree of M. D. Ten of these schools are in towns of between 30,000 and 40,000, two in towns of between 20,000 and 30,000, six in towns of between 10,000 and 20,000, and nine in towns of less than 10,000.

Ratio of Schools to Population.—There are 14 cities containing 4 or more schools each, and these cities contain 84 of the 154 schools. Below is a table of these cities, with population, number of schools and ratio of population to each school. The population in each instance is based on the census report for 1900. It is quite probable that the population of all of these cities has increased, but, if so, the relative increase is possibly about the same. It will be noticed that New York has the fewest medical schools in proportion to its population, and that Chicago has the distinction of having the largest number of medical schools of any city in the United States.

Table of Ratio of Colleges to Size of Cities.

City.	Population.	Number of Schools.	Ratio of Popu. to Each School.
Dallas	42,638	4	10,659
Nashville	80,865	5	16,173
Kansas City	163,752	6	27,292
Louisville	204,731	7	29,247
Indianapolis	169,164	4	42,291
Baltimore	508,957	8	63,619
San Francisco	342,782	5	68,556
Washington	278,718	4	69,679
Cincinnati	325,902	4	81,475

Chicago	1,698,575	14	121,326
Boston	560,892	4	140,223
Philadelphia	1,293,697	6	215,616
New York	3,437,202	7	491,029

THE IDEAL PRELIMINARY EDUCATION FOR MEDICAL STUDENTS.

That there is unusual interest in the education which prospective medical students are to pass through preliminary to undertaking the studies of the medical curriculum proper is proven by the large number of articles which are being written on the subject, by the discussions which take place in the faculties of medical colleges, and among the students of those colleges, by the action taken by the Association of American Medical Colleges as regards the minimum requirement, and, above all, by the high standards of admission which are being adopted by the schools of higher rank in various parts of the country. There can be no doubt that a strong movement has set in toward a more liberal education of the profession, as a whole, and that this movement is supported not only by the best representatives of the profession itself, but also by the more intelligent part of the public with which the profession has to deal. The reason for this movement may be found in the general elevation of educational standards and in the enormous advances in the medical sciences dependent on progress of knowledge in the fundamental subjects of biology, chemistry and physics.

Up to 1895 no medical school in the United States had rigorously demanded for entrance any educational qualifications higher than those corresponding to graduation from an ordinary high school. In that year the Johns Hopkins Medical School was opened, its faculty making the startling announcement that in order to gain admission to the school applicants must not only possess the bachelor's degree in arts or science from a recognized college or university, but must, in addition, present certificates indicating the completion of a year's work (including laboratory practice) in biology, physics and chemistry, and give evidence of the possession of a reading knowledge of the French and German languages. Great skepticism was expressed at the time regarding the advisability of setting up such a high standard even by a school which was liberally endowed and was not dependent for income on the fees of students. A prominent member of the staff of the school itself declared the entrance requirements to be absurdly high, and prophesied that not a student would apply for admission. However, a dozen students were enrolled during the first year, and the number has steadily increased, until last year there were nearly 100 students in its freshman class.

The success of this school in securing a large number of superior students, capable of beginning the subjects in the medical curriculum on a plane far above that on which they must be begun by students less liberally educated, has been perhaps the most potent influence in leading colleges like Harvard and Western Reserve, and after them, a group of other medical schools connected with universities, to require a college education, or at least some part of it, preliminary to the undertaking of medical studies. From these leading medical colleges the movement in favor of more liberal preliminary training is rapidly spreading into the rank and file; even the conservative Association of American Medical Colleges, with its large membership of widely distributed medical schools, at its last meeting adopted high school graduation as a minimum entrance requirement to become operative in the near future, a standard which five years ago would have been thought impossible of attainment.

* The statistics for these three years were obtained from the report of the Commissioner of Education.

It is easy to formulate the needs of the modern medical student in the way of preliminary education. In the first place, he should be liberally educated; in the second place, he should secure that liberal education at a relatively early age, in order that it may be followed by four or five years of the medical school and one or two years of hospital experience, or foreign travel, and the man not be too old when he enters on the actual practice of his profession; in the third place, he should receive training in certain special subjects—like biology, physics and chemistry—which are fundamentally necessary for a proper understanding of anatomy, physiology, pathology and bacteriology, for otherwise he will be compelled either to take up his medical studies in the non-scientific and superficial way which the lack of such training compels, or, in the medical school, he must spend a large part of the time which should be given to the more strictly medical subjects, to the acquisition of that training; and in the fourth place, beside having a good command of English, he should be able to read German or French, or both, in order that he may consult the original sources of a large portion of medical knowledge and keep pace with the advance of medical thought and practice in the great European medical centers.

If these are the real needs of the prospective medical student, how may the admission requirements to our medical schools be adjusted in order that the faculties thereof may feel confident that entering students have satisfied them? Different educators would doubtless answer this question in different ways, as opinions differ as to what may be regarded as "a liberal education." Many assume that it is synonymous with the bachelor's degree. Others maintain that graduation from the high school, the "people's college," should guarantee a sufficiently liberal education for entrance on professional life. The consensus of opinion among the more intelligent of the laity would probably consider the former view nearer its standard than the latter. A liberally educated man, it would say, must have received a more profound training in languages and literature, and in mathematics and the sciences than is obtainable in even the best of our high schools. A physician or a lawyer who can not use the English language with a tolerable degree of accuracy, who has little or no conception of the historic method, who is not familiar with the chief results and general trend of modern science, and who, in his contact with life, is unfamiliar with that literature which is the interpretation of life, must, it thinks, enter on his career more or less seriously handicapped.

Just here, though, the age difficulty is met. The average college graduate is about 23 years old. If he then study medicine four years, spend a year or a year and a half as a hospital interne, and then go abroad for a year to visit European laboratories and clinics, he will be nearly 30 years of age before he enters on his private practice. All will agree that at 30 a man should be actively engaged in the practice of the profession to which he is to devote his life, and many will maintain that the student who enters the medical school at 23 after four years of college will be more blasé and less plastic than the student who enters the medical college directly from the high school. Against these objections it is urged (1) that while the average age at graduation from college is 23, these figures give a false impression; the majority of students graduate at a much earlier age, the average age being higher owing to the presence in the graduating classes of a few men of 35 or 40 and over; (2) that time is now wasted in college and in high schools, and that if the curriculum in these were modified students might easily enter college at 16 or 17 and graduate at 20 or 21, and be as far on as the average college graduate is to-day at 23, and (3) that the greater success which is possible and the greater personal satisfaction derivable justify the student in prefacing his medical course by a thorough education in college.

The medical student who desires to take both the bachelor degree and the medical diploma has been much helped by the wise requirement made by certain schools that a training in chemistry, physics, biology, French and German shall precede medical study. Colleges preparing students for medicine have had to arrange their curricula so that premedical students may, during their three or four undergraduate years, obtain the necessary work in these subjects, for a baccalaureate degree obtained without them is insufficient to admit a student to that medical school. Indeed, the ordinary baccalaureate degree means so many different things with us that some of the better medical schools are of the opinion that two or three years of college work in which training in physics, chemistry and biology are included, make a far better preparation for medical study than four years of college work in which these subjects are omitted, and they have framed their admission requirements accordingly. The significance of the time element in this whole question is made sufficiently obvious by the various devices which have been introduced to shorten the period for obtaining a degree in arts and in medicine. The first method resorted to was to give the college graduate a year's advanced standing when he entered the medical school. If the baccalaureate had taken the science course this was a fair thing to do at a time when the admission requirements were so low that biology, physics, chemistry and even a little Latin had to be taught in the medical school itself, for the science work such a student had done was, as a rule, far better than he could get in the medical school. If he had not had a science course, the year of advanced standing was of doubtful advantage to him, for he had to crowd the work of four years into three. Now that physics, chemistry and biology are being crowded out of the medical school entirely and forced back into the college curriculum, any advanced standing to a college graduate in the medical school other than that corresponding to work of the medical curriculum itself which he may have previously accomplished is likely to be harmful to him; his course will be crowded with con-

flicts, and, instead of being a better student for his liberal college education, he may be seriously handicapped in his subsequent career.

A second method advised is that of shortening the literary college course to three, or even to two years. The regular undergraduate course at the Johns Hopkins College is a three-year course, and Harvard has an arrangement by which a good student may graduate in three years, instead of four, if he so elects. The president of Columbia University has suggested that the course be so arranged that the bachelor's degree may be given at the end of two years, but there has been a strong outcry against this proposition, and it has nowhere yet been put into practice. Pending the actual shortening of the college course, certain of the universities have practically accomplished the same purpose by establishing laboratories and professorships in the university corresponding to the subjects of the first two years of the medical curriculum and "telescoping" the two courses, so that the student may secure the two degrees, baccalaureate and medical, at the end of six or six and a half years of work; the student in the first two years gets his English, history, mathematics, physics, chemistry, biology and languages, at the beginning of the third year undertakes the first two years of the medical curriculum taught in the university as pure sciences, and at the end of the fourth year receives the bachelor's degree; by this time he has completed the study of the fundamental medical branches and is ready for clinical work, after the successful completion of two years of which he is given the M. D. degree. This plan is at the moment a popular one, for it has not only been adopted by richly endowed institutions, but has met with favor among some of the state universities, many of which are rapidly installing departments of anatomy, physiology and pathology, and are encouraging candidates for the bachelor's degree who propose to take up medicine to elect these subjects as the science work of the third and fourth years. Vigorous protests are everywhere to be heard against this method; many see in it the downfall of the American college and hear in it the deathknell of the time-honored classical course; some even urge that it is dishonest to count the work in anatomy, physiology and pathology toward both degrees.

How all this will ultimately work out we dare not venture to-day. It would not be surprising if later on, when the reforms now in progress in high school education have become effective, students should graduate from high schools a year earlier than they do now; then the college course may be reduced to three years and be differentiated after the first year, so that students looking forward to medicine will follow one course, those intending law another, those looking toward engineering another, and so on. Students would then begin their professional studies at 20 or 21 years of age, and would have behind them not only the liberal culture of the college course, but also that training in specific branches which necessarily precedes the more strictly professional chemistry, biology and languages, at the beginning of the fessions. We suggest this as a possible outcome; but the history of education is full of surprises, and it may well be that some entirely unexpected readjustment at present not conjecturable may be made.

THE MINIMUM REQUIREMENTS.

Above we have been discussing what might be called the ideal preliminary or premedical standard of education. Ideals are excellent, but actual practical life often has to fall far short of ideals. This may be said of the ideal preliminary training for the medical course—we can not yet make all would-be medical students realize the necessity of such an ideal education or force medical colleges to demand it. One thing is possible and essential, that is to fix a working minimum below which none can go, and then duly enforce this standard on all medical colleges. What appears to be a practicable and reasonable minimum at the present time is a good high school course, which must include a certain amount of Latin and living foreign languages.

There are, however, varying high school standards, and a high school diploma in one state or community represents a standard decidedly different from one in another state or community. There are high schools and high schools, and the mere possession of a high school diploma does not always guarantee that the minimum requirements have been attained. The solution of this difficulty is in the standardization of the high school course and the formation of a list of schools that come up to that standard.

But the most important part of the problem to be solved is: What shall be done with him who has no high school diploma or equivalent certificate? In the first place, the applicant must show by examination that he has an equivalent education. In the second place, and this is vital, the examination must not be in the hands of those who are interested in the student passing, viz., those connected with the medical colleges.

This principle must be emphasized, and the right to say whether a man is qualified or not must be taken from those colleges that are run on a purely commercial basis. As we can not separate these from those that are conducted in a scientific and professional spirit, it must apply to all. It seems to us that the plan should be to adopt in each state where there are medical colleges an examination, uniform in all states, conducted by examiners appointed by the boards of registration, as in Ohio, by the state superintendent of schools, or by a similar disinterested body or individual. This method has already been provided for in a few states, and it is to be hoped that it will not be long before it prevails in all. This must be attained by the boards of registration refusing to recognize colleges that do not demand such a certificate, whether the law of the state in which the college is located requires it or not.

We wish it understood that we are not discussing what we believe is the desirable qualification for entrance, but what should be insisted on and enforced as the minimum.

THE VALUE OF MEDICAL BIOGRAPHY TO THE MEDICAL STUDENT.

A true pedagogic method of medical instruction is still a desideratum. The curriculum is so crowded and the time so limited that the acquisition of facts is the first and almost the only consideration. The system generally adopted may make plodding workers, but it lacks the element of mental training that should enter into any system of education, professional or otherwise. The need of this is the greater when the professional student has not had the advantage of a preliminary liberal education that has cultivated the faculties here neglected.

A great teacher of medicine has said: "As the stream of knowledge grows more rapid, we teachers live too much—we have to, I suppose—in the swift current, and few of us have time, too few the inclination, to go upstream to the sources of our art and science, and yet there is not a question which comes before us that can not be most safely approached from the historic side. Even when time and opportunity are lacking for personal investigation, as they often must be to busy teachers, the attitude of mind counts for much . . . ." Unquestionably, much good may be done in stimulating the proper spirit in our students and in giving them a proper perspective by encouraging them to read about the development of medicine as it is made evident in that most interesting form of medical literature, namely, the biography of the masters of medicine and allied sciences. This is wholly rational and based on the most correct pedagogic principles. We do not have in mind so much the establishment of regular courses in medical history, as is urged from time to time, but rather the awakening of interest in the alluring field of medical biography by means of occasional lectures and addresses, and especially by the encouragement to read good books and articles of this character. There is abundant opportunity to direct the attention of students to this aspect of medical literature. The names of great teachers and investigators are mentioned in the class-room every day in connection with their theories and discoveries, many of which have been of epochal importance in the development of a particular branch of science and even of wider significance. What could be more natural for the teacher than to call attention to some of the striking facts and circumstances connected with the lives and the work of such masters in medicine at the same time as the students are directed to books and articles in which more extended information may be obtained? In smaller classes, more particularly those conducted according to the plan of the seminar, students can be asked to prepare sketches of the lives and of certain aspects of the life-work of the founders of and important contributors to the particular branch with which the class is dealing. This plan is followed with success in some of our schools. In such classes it is possible, too, to study the original, classical articles and monographs in which the master-minds of medicine record their observations and discoveries and which form the mile-posts in the onward course of knowledge.

Owing to lack of library facilities, but still more to lack of interest in the historic side of medicine on part of the teachers, the student is given too scant an opportunity to become acquainted with these real classics of medical literature and to benefit from the stimulus that comes with seeking knowledge at its very fountain-head, while sitting, as it were, at the feet of the real masters. And certainly the interest and insight are increased if at the same time he can know something of the lives of these great men, of the conditions under which they worked, and of the state of medicine at the time and in the country in which they lived. We are convinced that it is possible by simple means of this kind to create in many a student a real interest in biographic and historic medical literature an interest that will take on spontaneous growth as he realizes the increased power to grasp subjects when their study can be approached from the developmental side, to say nothing about the pleasure and inspiration that must be felt by the delver into the amenities of medicine. There is just as much of broad human interest and liberalizing influences in medical biography as in any other form of biography, and at the same time it gives the best and liveliest picture of the development of medical knowledge. If any one should doubt the truth of this statement let him read the charming stories of the pioneers of medicine, told with such literary skill by Sir Michael Foster in his Lane Lectures on the History of Physiology during the 16th, 17th and 18th centuries. This book really constitutes the history of scientific medicine during these centuries. The story of such men as Vesalius, Harvey, Malpighi, Borelli, Stensen, Mayow, Lower, Lavoisier and others, with their love of truth and their capacity for patient, honest work, should be in the hands of every student of medicine.

As other examples of important books of this character mention may be made of the series called "Masters of Medicine," which consists of a number of small volumes, each giving an admirable account of the life and work of a man like John Hunter, William Harvey, Edward Jenner, Sir James Simpson, Hermann von Helmholtz, Claude Bernard and others. A few moments daily given to the reading of books of this series will give the hard-worked student cheerful, invigorating and profitable respite from the irksome grind of his routine work in the class-room and laboratory. No better way can be recommended to obtain an insight into the beginnings of the science of bacteriology and its tremendous significance for medicine, human, veterinary, as well as vegetable, in all its bearings, than the study of the life

of Pasteur, to whose genius all will agree medical science owes more than to any other single person the creation of its most progressive epoch. The lasting influence for good, for the setting up of noble ideals, for inspiration to become productive in medical knowledge that the careful reading of a book like Vallery-Radot's Life of Pasteur may exercise on the plastic mind of the developing student can not be overstated! Its reading in connection with the course on bacteriology, for instance, will give to that study an interest that it otherwise must be difficult to arouse even by the most genial teacher. This is a book that will have a most wholesome influence, too, on the intelligent non-medical person in arousing interest in and proper appreciation of scientific investigation along medical lines. Unfortunately, the English translation by Mrs. Devonshire is rather expensive—$7.50. It is a book that ought to be within the reach of every medical student. Of other books of this class we have the Life and Letters of Thomas H. Huxley, of Charles Darwin; the Memoirs and Letters of Sir James Paget; "Jugend-Erinnerungen eines alten Aerztes," by von Kussmaul—a charming book—as well as many others. Then there are numerous shorter articles and addresses of a biographic and historic nature that reading of which by medical teachers and students, as well as physicians in general, will be found profitable and interesting. Most of these are easy of access either in medical journals or as separates. The Smithsonian Institution of Washington has reprinted a large number of contributions of this kind which can be obtained for a nominal sum. In this country, Osler has been and is a fertile author of most excellent biographic studies of American medical men, investigators and pioneers, generally in the form of addresses. The interested teacher with the proper "attitude of mind" will find it easy enough to bring material of this kind to the notice of his classes as proper occasions arise. Let us not forget that students of medicine, in the broadest sense, perhaps more than any other class of educated men, and certainly now more than ever before, must be "broadly liberal in order to be minutely special."

THE RATIO OF STUDENTS TO TEACHERS IN THE MODERN MEDICAL SCHOOL.

The greatly increased cost of medical education in those schools which are teaching modern medicine, in the broad sense, has been frequently commented on, and it is undoubtedly true that this cost has far outgrown the purse of the average student. In the last ten or fifteen years the tuition fees have been raised at least 50 per cent., but the cost of maintenance has been increased to a much greater degree, and it is said that in one institution the average cost for each student is nearly 125 per cent. more than the total fees paid by him. Present indications are, moreover, that the limit of expense for maintenance has by no means been reached, while the fees demanded by a few of the larger schools seem to be as near to the maximum as it is reasonable to exact of the average student. With this condition of affairs it is obvious that if our medical schools are to be maintained on such a basis as will enable them to offer instruction adequate to the demands of the time, larger endowments must be had either through private beneficence or from the state.

What is the explanation of this increase? Are these conditions temporary, or likely to continue for some time to come? Fundamentally, they are to be found in the increased length of the medical course in the broadening of medical science through the developments of bacteriology, etc., and in the change in methods of instruction, and especially in the introduction of laboratory and practical methods of teaching in the fundamental branches, and as well in the clinical branches, though as yet in less degree. New buildings have become necessary for the departments of anatomy, physiology, chemistry, bacteriology, pathology and pharmacology; expensive laboratory equipment, apparatus and supplies are required for the departments. But costly as these things are, they are, for the most part, permanent investments, and have been more than balanced by the increase in the income of the schools from fees. With the more progressive schools the most important item is the increase in the instructional force, and the change in the character of the faculty. Under the purely didactic plan of teaching which prevailed up to fifteen or twenty years ago—for the amphitheater clinic of those days was little more than an illustrative didactic lecture—one instructor in each branch sufficed for the whole student body whether it numbered 50 or 500 students. A faculty numbering 20 or 30 was a large one for those days, though not a few schools had an annual attendance of five or six hundred students. Only one member of the faculty, the professor of chemistry, devoted his whole time to teaching, and had, therefore, to be paid a salary, and in the majority of colleges the occupant of even this chair was a general practitioner, who taught without pay. The introduction of laboratory methods has made such an arrangement impossible. A didactic lecture in anatomy or chemistry may be about as advantageously delivered to 500 students as to 30, but the adequate supervision of their work in the dissecting room or in a laboratory of chemistry, physiology, bacteriology or pathology demands an instructor for every 20 or 30 students at the most.

Under the old régime, the larger schools possessed a great pecuniary advantage over the smaller ones. The faculty of a school of several hundred students was not of necessity, nor was it, in fact, materially larger than that of a school attended by 30 or 40 students. Yet the income from fees was several times as large. It was frequently urged as an argument in favor of the smaller schools that more intimate personal contact of the pupil and teacher was secured, and there was some truth in this assertion. The same statement is sometimes made at the present time, but a careful scrutiny of the facts

will show that the statement is, for the most part, no longer true. Single departments, such as those of anatomy or physiology in some of the larger schools, number almost as many instructors as sufficed for the whole faculty twenty years ago. Examination of the figures in five of the largest schools reveals the fact that the ratio of teachers to students is from 1 to 4 or 5, and that it is larger than in many institutions with an attendance of one to two hundred. It might be argued that the majority of these instructors are subordinate members of the faculty, but it should be noted that it is coming to be the custom in this country, as it has long been in Germany and other European countries, to recruit the faculty of the smaller provincial school from that of the larger metropolitan college.

It is not the initial cost of buildings and equipments, the expense of repair and renewal of which is slight, which constitutes the important item of cost in any enterprise. It is the constantly running annual outlay for salaries and the like which so rapidly amount to a large sum. This greatly increased ratio of teachers to students, together with the fact that so many of them must be paid a sufficient salary to enable them to live in the absence of other income, fully explains the great increase of the cost of medical education. In a few medical colleges some of the departments have several salaried instructors in each department, and the aggregate cost is readily seen to be great.

If, as many believe to be the case, similar provision of salaried professors and assistants must be made in the clinical branches, it is difficult to see how the modern medical school can be maintained without very large endowments from some source. The idea which has led to this great change may be briefly expressed as that of "group teaching" as opposed to teaching in "mass." The tendency of the times is all away from "mass teaching" —a method which obtained quite as much in the small as in the large college under the old order of things now passing away. Instruction in "small groups" is imperative under laboratory and practical methods, and such teaching is of necessity very costly.

MEDICAL TEACHING AND MEDICAL RESEARCH AND THE INCREASING OPPORTUNITIES IN AMERICA TO ENTER ITS CAREER.

This interesting subject is discussed briefly in the *University Record* of May, 1903. It is quite appropriate to continue the discussion in this, the educational, number of THE JOURNAL. The subject is of interest to every physician because it deals with questions that touch the vital center of medicine in this country; it is of interest to every medical student because he is concerned directly and personally with medical teaching, and, naturally, he must feel gratified if he learns that his opportunities to study medicine are better than those of his predecessors. The article in question points out that not so very long ago, indeed, only a few years ago, this country offered but one distinctly medical career to the student, namely, the practice of medicine in some form or other. It says:

> Twenty years ago there was but an insignificant number of salaried medical professorships; assistants were not necessary because the teaching was done almost wholly by didactic lectures; very little attention indeed was given to research in the medical schools, and endowments for medical research existed only in the dreams of the visionary. But within a remarkably short time a most marvelous change has taken place. The elevation of the standards of medical education, the introduction of laboratory methods in medical teaching, the fostering influence of our best universities, and the steadily increasing endowments of medical teaching and investigation are some of the most important elements in the growth that has led up to the present period of promise, the blooming period of medicine in America. Rapid and healthy development of this nature can not but be associated with an increasingly diversified differentiation of function, and so there is now larger opportunity than ever before for successful careers as medical teachers and investigators to the exclusion of the actual practice of medicine.
>
> Many of our best universities now offer practically the same inducements to properly qualified young men to join the departments of anatomy, physiology, pathology, and bacteriology, as they do in the case of the other university departments, let us say history, physics, chemistry, and zoölogy. In not a few instances positions in the medical departments just named are filled with success by men who have specialized in some one of these lines without having taken the regular courses in medicine. This fact is cited here simply to show that these fields offer welcome opportunities to qualified aspirants for academic careers.
>
> In the more purely clinical branches the conditions as yet are somewhat different. Professors and instructors in these branches rarely, if ever, give their time and energy undividedly to teaching and investigation, but combine this work with the arduous duties of private practice. But even in these branches, related so intimately to the practical work of the physician, indications point to new developments that before long may culminate in the establishment in some of our universities of departments of medicine, of surgery, and of obstetrics on the same general basis as other university departments. Necessarily this must lead to the foundation of university hospitals as well as to the creation of a large number of positions to be filled by specially trained men who are willing to devote themselves wholly to the teaching of the clinical branches and to the investigation of the many important problems that await solution in these fields.
>
> Then, again, the recent endowments of independent institutions for medical research will offer especially desirable opportunities for those whose ability and training fit them for the highest order of investigative work. The establishment, too, of research professorships in the universities may be found to prove advantageous in order to advance to greater opportunity the man of genius sure to appear from time to time as the number of men engaged in productive work in the medical sciences increases.
>
> Attention may be directed also to the fact that government and municipal services are demanding an increasing number of specially trained men to carry on their work, much of which is of the nature of research in various lines. The health departments of our larger cities need men trained in sanitary science; the Philippine civil government has established laboratories in which active investigation is carried on in the rich field of tropical diseases.
>
> The managers of many of our state hospitals for the insane are beginning to realize that the surest antidote to the fossilizing influence of routine and institutionalism is to be found in the reorganization of the medical work on a scientific basis so as to attract to this service men of scientific interests and training.

These statements represent the conditions as they are. As the advent of university ideals in medical education is with us as yet barely an accomplished fact, the opportunities spoken of in teaching, in research, in sanitary science are bound to widen more and more as time goes on. The fact that medicine now offers the talented, energetic, well-trained man something more than, and

different from, the chance to crowd into the ranks of the practitioner will attract men with broad training and high ideals. In order to make careers of the kind here discussed just as attractive as possible to the finest types of college student—for no one questions for a moment the importance of this new departure on the progress of American medicine—the question of financial remuneration should be considered most carefully. The prudent man, who must earn his livelihood, will hesitate to embark on an exclusively academic or scientific career unless it appears quite clear that he need have no special fear for the future. Inasmuch as the salaries paid men of this kind probably will not exceed greatly, if at all, those paid men of equal rank in other departments of universities—and such salaries are confessedly small—it is most desirable that some liberal system of pension for age, disability, specially meritorious service, or other cause be instituted. This would result in a feeling of security the importance of which can not be doubted.

HOSPITAL AND CLINICAL WORK.

In the majority of the articles that have appeared in this country on the desiderata of medical education, comparatively little stress has been placed on the clinical training that ought to finish off a medical student's course. Possibly the matter has appeared too self-evident to require special emphasis, but the omission is the more notable since this subject was the principal one discussed in a rather remarkable symposium on medical training published in the German periodicals four or five years ago, in which von Jaksch and several other prominent German physicians took part. The present agitation among German medical students on account of the coming exaction of the "practical year" taking effect in 1906, and which is, therefore, retroactive in the case of any who have matriculated within the past year or two, is in point. The necessity of more than mere theoretical training, and, indeed, that of actual hospital practice, is so far recognized in Germany that it has been made imperative.

The necessity of this requirement is no less in this country, but the facilities for meeting it are far inferior, and the total number of German medical students is hardly more than that of graduates here. How to furnish our five or six thousand annual diplomates with practical clinical instruction and with hospital positions is a problem. The colleges that can furnish only the theory, however richly endowed and supplied with well-qualified teachers, laboratory facilities, etc., will be at a distinct disadvantage. The hospital year means more than simply "walking the hospitals"; it means actual residence and responsibility, and all that that kind of training implies. Here the state universities, with their well-equipped laboratories, etc., unless they have their medical schools in or near populous centers, will, at least in many cases, be at a disadvantage; and this may materially modify the future of the medical departments of some of these institutions. How, on the other hand, it will affect the commercial, or what we may call the personal advertising medical colleges is another problem.

One thing we believe will result from the better recognition of this need—it will, like the state examinations, stimulate to better work, and those medical schools that best fit their students by giving them practical clinical experience, without which they are seldom fitted to take the responsibility of the lives and health of their fellow men, will be the successful colleges of the coming years.

AN EDUCATOR'S FORECAST OF FUTURE MEDICAL EDUCATION.

An eminent educator, President Jordan[1] of Leland Stanford University, in a commencement address, delivered at the Cooper Medical College, San Francisco, gives his views regarding the future of medical education in America. He says the two types of medical colleges in the future will be: One, the present type of which is the medical department of the Michigan University, the aim of which is to elevate the profession in the aggregate, taking men as they are, demanding not excessive, but respectable, preliminary requirements, and maintaining no standard impracticable for the average man, but turning out as well-qualified physicians as the material will allow. The other, the existing type of which is the Johns Hopkins School, will demand the highest preliminary culture and send out only a limited number of the very best into the profession. The former will be the type toward which he thinks the state universities will tend, while a few highly endowed private institutions will have the highest standard, and be special centers of medical science and research. "The practical evolution of the matter," he says, "will be this: The medical school for the exceptional student will require a college course of science with physiology and chemistry as the leading subjects; other sciences, with German and French, being necessary factors. The state medical colleges and those of similar purposes will content themselves with a minimum of two years of college work, along semiprofessional lines, the preparatory medical course." It will be seen from this that Professor Jordan takes no apparent account of the value of a classical education, the sciences in modern languages being, in his forecast, the essentials that will be demanded. Whether this prophecy will be entirely realized is perhaps a little open to question, and it may be that he underestimates the value of the preparatory medical course and the quality of those who will choose it. There are now, and always will be, some institutions that will demand the fullest culture as preparatory to professional studies, and probably in the near future such institutions will grant degress that will be more highly valued, if not nominally more distinguished, than those of the average school.

THE VALUE OF THE CLASSICS IN MEDICAL EDUCATION.

In view of the apparent disregard of classics, it is of some interest to see that in the laws of some of the states a certain amount of classical education is still considered

1. Popular Science Monthly, August.

an essential preparatory requirement. In the new Michigan law there is a provision that the applicant shall have, previous to beginning his course in medicine, "a diploma from a recognized and reputable high school, academy, college or university having a classical course, or shall have passed examination equivalent at least to the minimum standard of preliminary education adopted and published by the board, before the examiners appointed and in accordance with the regulations of the aforesaid board, and at such time and place as the board may designate." In the Maine law the minimum grade of preliminary education before admission to the study of medicine includes, besides the ordinary high school scientific studies, ability to read at sight common Latin prose. There are other regulations of similar import in the by-laws of some state boards, but these that we have mentioned are specified in actual legislation. We believe that the tendency will be to emphasize the importance of a certain amount of classical training, rather than the reverse. Bearing on this point, as we have noticed elsewhere, certain fears have been expressed in Germany because of the admission of graduates of *Realschules,* or non-classical high schools, to the study of medicine. These fears prove to have been groundless because it is found that only a comparative few of such choose the profession of medicine. A certain knowledge of Latin and Greek, at least as much as is required for admission to the freshman class of a good university, is almost essential to the medical man, and more would certainly be very desirable. There is nothing that helps more in the acquirement of the modern languages than some knowledge of the classics, and modern languages are, to a certain extent, indispensable to the high-class medical education.

A FEATURE OF THE MICHIGAN PRACTICE ACT.

It will be remembered, in regard to the Michigan medical law, that when the Nottingham act was first introduced it contained a provision requiring graduates of medical schools of foreign countries which do not recognize the Michigan diploma to undergo a course in Michigan schools, the law corresponding to that of certain provinces of the Dominion of Canada, and was intended to apply to those coming from that country. This was objected to, and considerably criticised by newspapers and others at the time. As the law now reads, an applicant for examination must have a diploma from a legally established and reputable college of medicine in the United States or some foreign nation, "provided such foreign nation accord a like privilege to the graduates of approved medical colleges of this state." In effect, this leaves the matter very much as in the original bill. It will be hard to see how a graduate from a Quebec college, for example, or, indeed, from any foreign country, can be admitted to examination in Michigan under the law. It leaves out, however, the objectionable passage in regard to their having to study in Michigan institutions, which was really copied from certain Canadian provincial laws, and it has not the appearance, therefore, of being drawn up to favor home industries. So far as appearances go, it is a measure of reciprocity, or rather of non-reciprocity, with countries which do not recognize the Michigan diplomas. If we read the law aright, foreigners will have no show hereafter in Michigan.

MEMORIAL TO MAJOR WALTER REED.

A meeting of the committees appointed by the American Medical Association and the American Association for the Advancement of Science has been called to meet at Bar Harbor, Me., August 15, to confer regarding the memorial in honor of the late Major Walter Reed, M.D. There are other committees beside the ones above mentioned, and the object is to secure immediate, concerted action and unanimity of purpose. The chairman of the committee representing the American Medical Association is Dr. W. W. Keen, Philadelphia, and Dr. Daniel C. Gilman, Baltimore, is chairman of the committee representing the American Association for the Advancement of Science. It is to be hoped that the various committees will be heartily supported by those whom they represent, and that in the immediate future a memorial worthy of the man and his work will be dedicated to Major Reed.

Medical News.

CALIFORNIA.

Prison for "Herb King."—"Dr." Frank N. Martin, who dispensed herb medicines as the "Herb King," and referred to in these columns before, was sentenced to thirty years' imprisonment in the state prison at Folsom, for rape committed on a feeble-minded girl who was under his care.

More Bubonic Plague.—Since June 5, three more cases of bubonic plague have occurred at San Francisco, making 98 in all. Pietro Brancota died at 19 Jasper Place, July 20; Pietro Spadafora, son of above, was taken from same address and died at Southern Pacific Hospital; Chin Guie, a native of China, died at 743 Jackson street, July 15.

MARYLAND.

Unlicensed Practitioner Arrested.—W. S. Howard, Vale Summit, was arrested in Frostburg, July 22, charged with practicing medicine in Allegany County without having obtained license from the State Board of Medical Examiners, and with having failed to register with the county clerk. He was held in $300 bail.

The Cumberland Epidemic.—Dr. Francis P. O'Neil, Baltimore, who attended the smallpox cases at the Emergency Hospital in Cumberland for 51 days, has rendered a bill for $512.50, which the city council has ordered paid. There were 41 cases from the city and 6 from the surrounding country. But 2 remain, and they are about to be discharged. The total cost of the epidemic to the city was $5,000.

Baltimore.

New University Building.—The plan for the new building of the University of Maryland provides for a four-story brick structure, 100 by 90 feet, to cost $50,000. The basement and first and second floors will be used by the dental department. The other floors will be used by the medical department for bacteriologic and other laboratories.

Personal.—Dr. J. Williams Lord has resigned the chair of clinical dermatology in the Baltimore Medical College, and Dr. Edgar R. Strobel has received the appointment.——Dr. Nathan E. B. Iglehart has gone to Muskoka, Canada, for a month.——Dr. Albert L. Levy has been appointed resident physician to the Hebrew Hospital, vice Dr. Nathaniel G. Kierle, Jr., resigned, to go abroad.

July Statistics.—During July the health department reported 1,097 deaths and 782 births. There were 506 deaths under 5, or 46.12 per cent. Only one case of smallpox was reported. The chief causes of death were: Typhoid fever, 19; scarlet fever, 11; whooping cough, 9; diphtheria, 8; dysentery, 7; cancer, 40; apoplexy, 36; heart disease, 60; pneumonia, 41; tuberculosis, 121; Bright's disease, 58; suicide, 5; puerperal

septicemia, 6; and diarrhea and enteritis, 233. The deaths for the week ended August 8 were only 179.

MASSACHUSETTS.

Personal.—Dr. Louis A. Prefontaine has been appointed oculist to the Springfield Hospital, sharing that position with Dr. Ralph Carleton.

New Gift to Milford Hospital.—Mr. E. S. Draper has authorized the erection and equipment of a chemical and bacteriologic laboratory for the Milford Hospital recently built and equipped by him and presented to the town.

Home for Insane Colony.—Ground was broken, July 30, for the building for the Grafton colony of the Worcester Insane Asylum, at the intersection of the town lines of Shrewsbury, Westboro and Grafton. The building will accommodate sixty patients. It is planned that the colony shall so develop as to accommodate in a few years from two to three thousand patients.

Boston's Vital Statistics.—During the week ended August 8, a marked improvement was shown over the week before and also over the corresponding week of last year. The deaths reported were only 170, a rate of 14.70 per annum per 1,000. There were reported 30 cases of diphtheria, with 1 death; 15 cases of scarlet fever; 25 cases of typhoid fever, with 3 deaths; 20 cases of measles, and 14 cases of tuberculosis and 10 deaths. Pneumonia caused 13 deaths; heart disease, 13; bronchitis, 2, and marasmus, 7. Of children under 1 year, 60 died and 77 under 5 years.

MICHIGAN.

Smallpox.—Bay City reports several cases and one death.——Houghton County, after a three years' siege, is now free from the disease. About 65 cases have been treated in the isolation hospital since the first of the year, with no deaths.

Old Doctors Long Married.—Dr. J. D. Bear, Detroit, fifty-nine years married, celebrated his eightieth birthday anniversary, July 31.——Dr. and Mrs. William H. Haze, Lansing, recently celebrated the sixty-third anniversary of their marriage, Dr. Haze is in his eighty-seventh year.

Michigan Tetanus.—The State Board of Health is endeavoring to collect facts relative to the prevalence of tetanus in the state, to the exact mode of its causation, and to publish the facts thus obtained for the information and protection of the people. To this end it has prepared and issued a special blank to contain the final report of each case of tetanus reported in the state.

Personal.—Dr. Alfred M. Switzer, Grand Rapids, has resigned as city physician and has been succeeded by Dr. Ralph C. Apted.——Dr. Rush McNair, Kalamazoo, is taking post-graduate work in Edinburgh and Paris.——Dr. Charles C. Wallin has been appointed city bacteriologist of Grand Rapids.——Dr. James R. Arnell, Ann Arbor, formerly instructor in internal medicine at the University, has been appointed associate professor of medicine in the University of Colorado, Boulder.

MISSOURI.

Serious Accident to Physician.—Dr. Kearan C. Cummins, Maryville, after throwing down hay to his horse, was impaled on the tines of the pitchfork, one of which passed through his body, narrowly missing the kidney.

Typhoid Gaining Ground.—St. Louis reports for the four months from April to July inclusive 444 cases of typhoid fever with 74 deaths. In the same period of 1902 there were 197 cases with 46 deaths, and in 1901, 131 cases and 31 deaths. The City Hospital now has 21 typhoid cases.

Personal.—Dr. Lyman T. Reber, for eight years mortuary clerk of the St. Louis Department of Health, has resigned to enter private practice.——Dr. Edward C. Runge, superintendent of the St. Louis Insane Asylum, has resigned, and will accept a position tendered him at the Government Hospital for the Insane, Washington, D. C.

Registration of Consumptives.—An ordinance became law in Kansas City, July 24, without the approval of the mayor, which provides that all persons suffering from consumption in an infectious stage must be registered with the board of health, and must follow the instructions as to isolation and treatment made in each case by the city physician. The lay press says that the law is aimed primarily at the negroes, a large percentage of whom have consumption, and who in their conduct on the streets and in crowds show no care for the danger to public safety from the germs of the disease.

NEBRASKA.

Fire in Physician's Office.—A fire which is said to have started in the office of Dr. Chester D. Barnes, Tecumseh, resulted in damage amounting to $15,000.

Banished from Lincoln.—Edward C. Smith and Gustav Ephraim, styling themselves the "Wonderful Gentile and Jew Healers," and posing as instantaneous and permanent healers of all diseases, were summarily expelled from Lincoln.

Personal.—Dr. J. V. Bechtol, for many years at Friend, has just returned from taking a two months' post-graduate course in New York, and has located at Hastings.——Dr. E. E. Robbins, Ord, has been appointed third assistant physician at the Asylum for the Insane, Hastings.——Drs. Alonzo E. and Lucinda C. Mack, Omaha, have returned after an absence of several months abroad.

Recommend Revocation.—The secretary of the State Board of Health, on August 6, recommended the revocation of the license of Dr. Charles W. Downs, Omaha, for violation of the law forbidding the distribution of advertising relating to sexual diseases which tended to corrupt the morals of people. The advertising is considered of a particularly vicious nature. Downs appeared before the board and made the defense that he did not know there was such a law.

NEW YORK.

Gives Addition to Hospital.—Congressman Littauer has given $25,000 for an addition to the Nathan Littauer Hospital, Gloversville, which he erected several years ago as a memorial to his father.

After Suit, Compromise.—Dr. Charles F. Wicker, Saranac Lake, who sued the village for $1,200 on account of care of smallpox cases last year, and was given a judgment of $1,100 and costs, has agreed to settle for $1,000.

Artesian Water for Ithaca.—On August 6, the Board of Water Commissioners began the distribution of artesian water from wells owned by the city, charging one cent a gallon. Before long it is believed that the artesian water will be supplied to the citizens through the mains of the Ithaca Waterworks Company.

New York City.

No Race Suicide.—Health department records for the week ended July 25 show 1,121 births and 613 deaths in Greater New York.

Daily Medical Journal.—It is announced by the lay press that Dr. Albert W. Ferris and six other New York physicians have formed a company for the publication of a daily medical journal, the first number of which will appear October 1.

Rosenbaum Litigation to Cease.—The litigation over the estate of Mrs. Rosenbaum, valued at $30,000, which was left by will to the German Hospital, is to be closed. Mr. Rosenbaum contested the will, and after his death, his executor endeavored to prevent the hospital from taking possession of the property. He has now, it is said, agreed to give a clear title.

PENNSYLVANIA.

Diphtheria Epidemic.—An epidemic of diphtheria is said to prevail in several boroughs of Delaware County. A number of deaths have been reported, a large proportion of which are from the so-called "black" diphtheria.

Sues for Detention in Isolation Hospital.—Because he was forced into the pesthouse at Schuylkill Haven, Frederick Hinckle has brought suit for $10,000 damages against that borough. The plaintiff claims that he did not have smallpox on admission, nor did he contract smallpox while there.

Pure Food Prosecutions.—Prosecutions have been begun by the State Dairy and Food Commissioner against six Philadelphia firms for alleged selling of beer adulterated with salicylic acid.——A warrant has been issued against a firm of large wholesale liquor dealers charged with selling for blackberry brandy a compound colored by a coal-tar product.——It is hoped by many that the activity of the commissioner will have a widespread influence in arousing public sentiment, and will draw the attention of the National government to the need of general measures against adulterated foods and beverages.——The report of the department for July shows that during June, of the 63 samples of butter analyzed 44 were pure and 19 bogus; 93 samples of lard tested showed 44 pure and 49 impure or imitation; of 68 samples of milk and cream analyzed only 41 were found pure. Sixty-nine prosecutions were brought, 36 of which were in Philadelphia.

Philadelphia.

Resolutions Regarding Dr. Parish.—The faculty of the Woman's Medical College has adopted resolutions eulogistic of the late Dr. William Henry Parish, professor of anatomy in that institution.

Typhoid and Smallpox.—The official record of the board of health for the week ended August 8 showed that 36 new cases of smallpox had occurred, with 5 deaths. The new cases of typhoid fever numbered 108. The prevalence of the latter disease is ascribed to the promiscuous drinking of water at nearby pleasure resorts. The department of health is vigorously carrying on its crusade of vaccination. Some fear is felt that unless the disease is gotten under control before the onset of cold weather, there will be a serious outbreak.

Pasteurizing Plant in Operation.—The pasteurizing plant, the object of which is to supply pure food to the infants of the poor, and which was established by the benevolence of Nathan Straus of New York and of many Philadelphians, was put into actual operation on August 5. Dr. A. R. Green of New York inspected the establishment, and found it in excellent condition. The capacity of the laboratory is 15,000 bottles of pasteurized milk daily. The milk will be sold at the laboratory or at distributing stations at one cent a bottle. Persons who are unable to pay this sum may obtain milk for infants free, by producing evidence that they are worthy.

No Habeas Corpus for the Quarantined.—A writ of habeas corpus brought to obtain the liberty of Norman R. Hyland and family who are under smallpox quarantine in their home, and who were said to be starving, was dismissed. The quarantine was necessitated by the persistent refusal of the man to have his child suffering with smallpox taken to the Municipal Hospital for treatment. Judge Davis, in concluding his decision that the board of health has a right to quarantine the house, commenting on the destitute condition, said that "if provision is to be made for families under quarantine in their homes, there would be danger of many families being under quarantine 365 days in the year."

GENERAL.

Proposed Bureau of Medicines and Foods.—The following preamble and resolutions were presented to the American Pharmaceutical Association, at its recent meeting at Mackinac Island, by Dr. H. H. Rusby, chairman of the committee appointed to consider the proposition to create a Bureau of Medicines and Foods:

WHEREAS, The foods and medicines supplied in the United States do not so uniformly agree with proper standards of purity, quality and strength as they should, and

WHEREAS, A degree of distrust and want of confidence concerning the quality of such foods and medicines prevails to a discouraging extent, therefore, it is

RESOLVED, That a more perfectly organized system for remedying the above-mentioned conditions than that now existing should be devised and put into operation, and

Resolved, That the American Pharmaceutical Association and the American Medical Association, acting in harmony with the United States government authorities, constitute the most competent and trustworthy means for attaining the objects named, and

Resolved, That the American Pharmaceutical Association shall co-operate to this end with the above institutions, provided, that a plan be devised satisfactory to those institutions, and that the committee of this association be continued and instructed to report to the council. In the event that a plan satisfactory to the council of this association be reported to it previous to the next meeting of this association, said council shall be authorized to elect from the members of the American Pharmaceutical Association a board of directors consisting of five members to act with a similar board, in the event of its appointment by the American Medical Association and with the United States government authorities, in the establishment of a National Bureau of Medicines and Foods, and this council shall immediately on the election of such board report the same to the President of the American Medical Association, and

Resolved, That in carrying out these resolutions the following general principles shall be adhered to:

1. That neither this committee nor the proposed board of directors shall have authority to draw on any funds of the American Pharmaceutical Association.

2. That the methods employed for obtaining the objects stated above may include commendation of worthy products, or condemnation of unworthy ones, or both, provided that said methods of condemnation do not in any way involve the American Pharmaceutical Association in legal responsibility.

3. That nothing to be undertaken by such a bureau shall be in conflict with the spirit of the United States Pharmacopeia or with the United States government authorities.

4. That the operation of the proposed bureau shall be free from any attempt to secure financial profit for any of the institutes named herein nor for any of their members or agents; but said bureau is authorized to employ proper means for securing the funds necessary to defray its legitimate expenses.

On motion of Mr. Diehl the preamble and first resolution were adopted, and the whole referred to the council for action. The council recommended that the committee be continued.

FOREIGN.

The "Practical Year" Regulation.—The protests of German medical students against the retroactive feature of the "practical year" regulation, continue. They have been sent to the imperial chancellor from the universities of Bonn, Kiel, Munich and Wurzburg, and others are likely to follow.

French Congress Against Alcoholism.—The first session of this organization will be held October 26 to 29, 1903, at the great amphitheater of the Faculty of Medicine at Paris. It includes all persons and organizations interested in counteracting the ravages of alcoholism. The program includes the discussion of the actual situation and of the present status of the combat against intemperance, the public legislation and private initiative.

Regulation of Proprietary Remedies.—The Hamburg senate has passed an ordinance prohibiting any testimonials or recommendations on the wrappers or receptacles of proprietary remedies, and requiring thereon the name of the drug, the name of the firm preparing it and the price. Dealers are prohibited from repeating prescriptions of such remedies, and those which are to be on order of physicians must have that fact stated on the wrapper. Violations of the law are punishable by a fine of up to $36, or a corresponding period of imprisonment.

Pasteur Institute at Breslau.—There is to be added to the Hygienic Institute of the University of Breslau, under the direction of Professor Flügge, a department for antirabic treatment. This is the result of the experience, during recent years, of the Silesian province of Prussia, where bites of rabid animals have been unusually frequent. It is in the Districts of Oppeln and Breslau that most of these casualties have occurred. Of a total of 263 cases in 1898 in all Prussia, 102 occurred in Silesia; of 303 in 1899, 121; of 233 in 1900, 64. Heretofore, there has been but one Pasteur institute in Prussia, that in the Institute for Infectious Diseases at Berlin.

To Test Typhoid Prophylaxis.—The German reichstag has appropriated $20,000 for a test of the methods of Koch against typhoid. The investigations will be made chiefly at Strassburg, Landau, Saarbrück, Metz and Trier. Koch's plan is based on the early recognition of the disease, rendering it possible to isolate the patients and thus prevent infection. Especially should the ambulatory cases be looked after, as the least affected of these may spread the infection. Koch has also recommended special bacterial stations in the typhoid infected regions, which should work hand to hand with the general practitioners in determining the earliest appearances of the disorder.

Character of Medical Students.—The *Chronik* of the Berlin University says that the fears some have felt in regard to the admission of graduates of the *Realschules* (the non-classical high school) to the medical studies, have thus far been without basis. In the first semester of last year there was not a single one of these students in the medical classes, against 44 in the law schools. In the next semester we find some realschule graduates studying medicine, but the law students are in a very marked majority. The true *Realist,* says the *Allg. Centralzeitung,* chooses for his life occupation the one that affords him the best prospects, this, at the present time, excluding a few exceptional cases, is not the profession of medicine and the knowledge of this fact happily is not limited to the medical students alone.

The Statistics of Medical Students in Germany.—There are, at the present time, according to the *Klinisch-Therapeutische Wochenschrift,* 6,257 medical students in Germany as against 6,398 last winter, and 6,749 in the summer semester, 1902. Although every year shows a decrease in the number of students, still there is a strong over-production of physicians, if one takes into account the proportion between the population and physicians. The natural increase of the population, being yearly about half a million, would warrant a yearly addition of 250 physicians, and then there would be no lack. If all the matriculants of the present time complete their courses there will be yearly about 1,250 physicians sent out, about five times the number actually required. At the present time the number in the respective institutions are: München 1,003, Berlin 976, Leipzig 433, Freiburg 421, Würzburg 396, Kiel 317, Heidelberg 311, Bonn 242, Strassburg 237, Tübingen 207, Breslau 204, Erlanger 201, Greifswald 197, Königsberg 196,

Halle 180, Marburg 176, Giessen 158, Göttingen 150, Jena 131, and Rostock 121.

LONDON LETTER.

Physical Degeneration of the Urban Population—Enormous Proportion of Unfitness for Military Service.

The physical degeneration of the population is a subject which of late has received much attention both in the medical and lay press and been a matter of concern to several writers. The Journal has referred to it before. Alarm is felt at the fact that an enormous number of the town-bred population are unfit for military service. A parliamentary paper by Sir William Taylor, director-general of the Army Medical Service, which has just been published, throws some light on the subject. During the period 1893-1902 there were examined for enlistment 679,703 men, of whom 234,914 were rejected as medically unfit for service, giving a rejection ratio of 34.6 per cent. Sir William Taylor states that no record is kept of the number of men turned away without being examined, but that the number is a large one, though whether it would bring the number rejected up to 60 per cent. he can not say. The majority are rejected on account of poor physical development, namely, under chest measurement, defective vision, under weight, under height, imperfect constitution and debility, disease of veins, disease of heart, defects of lower limbs, varicocele, flat feet and loss and decay of teeth. Bad teeth and flat feet occupy a comparatively low place on the list of causes. But with regard to decay of teeth the number has increased in the last four or five years. It has been estimated that as much as 77 per cent. of the population, or 25,000,000, now live in towns. Of this number probably at least 6,000,000 appear to live in such poverty as to be unable to rear their children under conditions favorable to health.

Revised Classification of the Causes of Death.

We have called attention before (The Journal, May 10, 1902, p. 1242) to the new official list of the causes of death. Every effort is being made to render official statistics as accurate as possible. The registrar general has just issued another memorandum on the subject. The use of the term rubeola for measles is condemned, morbilli being the only Latin equivalent recognized by the Royal College of Physicians. In cases of peritonitis the cause, such as hernia, perforating ulcer, appendicitis or metritis should be stated. When a practitioner returns a cause of death as simply peritonitis, an official form is sent to him requesting a statement of the probable cause of the disease.

Infant Mortality in Bombay.

Dr. D. R. Bardi has recently read before the Bombay Medical and Physical Society an exhaustive paper on infant mortality in that town. In 1899 the infant mortality was 593 per 1,000 births. This appalling loss of life is due to overcrowding, bad sanitation, and above all to ignorance and superstition, which can be efficiently dealt with "only by sustained and organized efforts on the part of the government and the municipality no less than the public at large."

Miscellany.

The Ill Health of Richard Wagner—A Correction.—A typographic error occurs on page 372, line 43, first column, of The Journal of August 8. Instead of "Any spectacles he could get would have neutralized," etc., read: "Any spectacles he could get would *not* have neutralized," etc.

Are There Too Many Physicians?—There seems to exist a general complaint at present, and it appears to be reflected in medical journals to an extent which shows that the matter is almost universal and one on which there is a certain unanimity of opinion. We allude to the plaintive howl raised by a number of physicians concerning the overcrowding of the profession and the large number of physicians who are practicing medicine or attempting to do so. This wail naturally leads us to inquire whether there are, in reality, too many physicians. Of course, this leads to a critical inquiry into the terms which enter in the proposition, and the first one is as to what constitutes a physician. Any one who calls himself such or who can dignify his name with the affix "M.D." is not necessarily, on that account, a physician. There seems to unfortunately exist an idea that the mere fact of graduating at a medical college makes a physician; when, as a matter of fact, it merely qualifies the individual to begin studying in a rational manner. The title conveyed by the degree, in too many cases, reminds us of the old cynic's aphorism, *doctor sed non doctus*. The recent graduate who assumes learned looks and indulges in technical phrases is soon uncovered, and the veriest tyro soon discovers his deficiencies. He is soon relegated to the great band of physicians who have no practice, and it is this very fact which has led to the mistaken idea that there are too many physicians. Again, there are those who are employed to do what might be termed semi-medical or purely office work, and these certainly can not be looked on in the light of physicians. Another cause of complaint arises from the older members of the profession who are unreasonable in their querulous observations. They forget that they have not kept abreast of the progress made in the medical and surgical sciences and that they have remained in the same old rut, depending on their imperfect methods of examinations and on therapeutics which long ago were abandoned on account of their inefficiency. The younger generation has been trained to exact methods, in scientific diagnosis and modern rational methods of treatment. These causes have naturally contributed to a marked lessening of the practice and diminution in numbers of the patients of the older physicians, who but too often are derisively called "moss-backs." For them, there are too many physicians. They have felt the oncoming of a more competent generation of medical practitioners—*Hinc illæ lachrymæ!* We hardly think that there are too many physicians—we know that there can not be too many good ones. In this matter, as in all others, the law of evolution will hold. The weakest will go to the wall and the better, and, therefore, stronger portion will fittingly exemplify the law of the survival of the fittest.—*St. Louis Med. and Surg. Jour.*

Marriages.

Robert Granger, M.D., to Mrs. Lulu Howe, both of Cincinnati, August 6.

Jacques Holinger, M.D., to Miss Cora Follen, both of Chicago, July 29.

James S. Covey, M.D., to Mrs. W. F. Cochran, both of Culleoka, Tenn., August 6.

Elizabeth Janet Child, M.D., Bethel, Vt., to Dr. Daniel Freeman of Chicago, August 6.

Carroll McGinnis, M.D., Starbel, Ohio, to Miss Louise Himmelrath of Cincinnati, July 27.

Kate B. Gardner, M.D., to George W. Heumann, M.D., both of St. Louis, at Clayton, Mo., July 29.

Howard J. Williams, M.D., Muskogee, I. T., to Miss Sarah Annette Barnum of Kansas City, Mo., July 28.

Deaths.

Francis Turquard Miles, M.D. Medical College of South Carolina, 1849, of Baltimore, died, July 30, after a year's illness, from prostatic disease and multiple neuritis, aged 76. After studying in Paris he entered the faculty of his alma mater, filling successively various positions until 1860, when he became professor of physiologic anatomy. He served throughout the Civil War in the Confederate Army, being a surgeon the last year. At the close of the war he resumed his practice, and again visited Europe to study nervous diseases. He removed to Baltimore in 1868. He was appointed professor of anatomy in Washington University Medical School and later professor of anatomy and clinical diseases of the nervous system at the University of Maryland. In 1880 he was transferred to the chair of physiology, from which he resigned in 1903, on account of ill health. Dr. Miles was a member of the Medical and Chirurgical Faculty of Maryland, and had been vice-president. He was president of the American Neurological Association from 1880 to 1882; he was an honorary member of the American Associaton of Physicians, and had been a consulting physician of the Johns Hopkins Hospital since its foundation in 1889.

John Washington Divine, M.D. University of Nashville, Tenn., captain and assistant surgeon in the United States Army during the Civil War, and thereafter a practitioner of Tazewell, Tenn., died at his home in that place, from prostatic disease, July 28, after a long illness, aged 66. The Claiborne County Medical Society, of which Dr. Divine was a member, at a meeting, August 3, passed suitable resolutions in his memory.

Reuben Barney, M.D. Albany (N. Y.) Medical College, 1865, a member of the American Medical Association, the Medical Association of Missouri, and the International Association of Railway Surgeons, some-time president of the Chillicothe Board of Health, and of the city and county and Grand River district medical societies, died at his home in Chillicothe, Mo., July 16, from endocarditis after a short illness, aged 59.

Francis L. Morhard, M.D. Eclectic Medical College of the City of New York, 1896, a dentist of New York City, was instantly killed at his summer home at Stapleton, Staten Island, by an electric shock received while he was presumably endeavoring to adjust an imperfectly insulated wire in his cellar, aged 37.

Headley V. McNeer, M.D. College of Physicians and Surgeons, Baltimore, 1885; Bellevue Hospital Medical College, New York, 1886; a member of the American Medical Association, died at his home in Bramwell, W. Va., July 17, after an illness of two days, supposed to have been due to a ruptured abscess of the kidney.

Joseph Ferguson, M.D. University of Pennsylvania, Philadelphia, 1866, formerly medical director of the Pennsylvania Division, G. A. R.; surgeon of the Lady Franklin Alaska expedition in 1866, and author of "Life Struggles in Rebel Prison," died in Philadelphia, July 25, aged 63.

Fife Fowler, M.D. University of Aberdeen, Scotland, 1858, one of the founders and dean of the Royal College of Physicians and Surgeons, Kingston, Ont., and president of the Ontario Medical Council in 1892, died at his home in Kingston, August 2, aged 80.

George H. Greene, M.D. University of Michigan, Ann Arbor, 1865, a member of the American Medical Association, and once president of the Calhoun County (Mich.) Medical Society, died at his home in Marshall, after an illness of five months, aged 62.

John J. Taylor, M.D., for fourteen years secretary of the La Salle County Medical Society, and once president of the North Central Illinois Medical Association, died at his home in Streator, Ill., August 3, from cancer of the stomach.

James R. Gregory, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1887, Long Point, Ill., died at Las Vegas, N. M., where he had gone in the hope of improving his health, August 1, from consumption, aged about 40.

William V. Tolley, M.D. Central College of Physicians and Surgeons, Indianapolis, 1881, of Indianapolis, died at the isolation hospital in that city from smallpox, July 25, after an illness of several weeks, aged 67.

John E. Sutcliffe, M.D. Bellevue Hospital Medical College, New York, a resident of Louisville, who retired from practice in 1845, on account of defective vision, died at his home in Louisville, July 24, aged 83.

Delos W. Hoskins, M.D. New York Homeopathic Medical College and Hospital, 1895, formerly of Auburn, N. Y., died from consumption at Le Grand, Cal., in July, after an illness of four years.

Joseph Smith Carter, M.D. Ohio Medical College, Cincinnati, 1850, who retired from practice twenty years later on account of ill health, died at his home in Urbana, Ohio, July 27, aged 78.

John Henry Helfrich, M.D. Pennsylvania Medical College, Philadelphia, 1861, died at his home in Allentown, Pa., July 29, from Bright's disease after an illness of six months, aged 83.

Edwin Garrett Hank, M.D. University College of Medicine, Richmond, Va., 1898, died at his home in Tannerscreek, Va., from the effects of the kick of a horse, July 26, aged 27.

Albert Jeremiah Schureman, M.D. New York University, 1872, of Newark, N. J., died at the home of his brother in that city, July 28, after an invalidism of ten years, aged 74.

Amos C. Erskine, M.D. Central College of Physicians and Surgeons, Indianapolis, 1880, died at his home in Indianapolis, July 23, from tuberculosis, after a long illness, aged 55.

Milo Hotchkiss Jones, M.D. Yale University, New Haven, Conn., 1896, died at his home in Greenwich, Conn., from typhoid fever after an illness of one week, July 27, aged 28.

Walter D. Anderson, M.D. Harvard University Medical School, Boston, 1864, president of the local board of health, died at his home in Vallejo, Cal., July 31.

William E. Forest, M.D. New York University, 1876, formerly of New York City, was drowned at Rockaway Beach, July 28, while bathing, at the age of 53.

John C. Luke, M.D. Cleveland Medical College, 1871, for several years postmaster at South Fork, Pa., died at his home in that place, August 2, aged 70.

William Craig, M.D. University of Pennsylvania, Philadelphia, 1871, died suddenly at his home in Mentone, Cal., July 25, from hemorrhage, aged 83.

William H. Coyle, M.D. Cleveland Medical College, 1869, died suddenly at his home in Columbia City, Ind., July 29, from apoplexy, aged 68.

Benjamin Hawker, M.D. Eclectic Medical College of the city of New York, 1875, died at his home in New York City from diabetes, July 31.

Samuel W. Hoover, M.D. University of Michigan, Ann Arbor, 1885, of Fayette, Ohio, died suddenly, July 18, from paralysis, aged 46.

James D. Donnelly, M.D., 1848, died at his home in Mountain City, Tenn., June 18, after an illness of two years and a half, aged 79.

William M. Mercer, M.D. University of Buffalo, 1872, died at his home in Corunna, Ind., July 24, aged 75.

State Boards of Registration.

Pennsylvania Summary.—Of the 392 candidates who recently took the examination before the Pennsylvania State Board of Medical Examiners, 339 were successful, 50 failed to secure the necessary 75 per cent., 1 was expelled for cheating, and 2 withdrew because of illness.

Utah Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports that a written examination was held at Salt Lake City, July 6 and 7, 1903, at which the number of subjects was 10; questions, 80; percentage required to pass, 75; total number examined, 7; all of whom passed.

EXAMINATION QUESTIONS.

Lists of Questions Asked at State Board Examinations.

We give below the questions asked by the Ohio State Board of Medical Registration and Examination at Columbus, June 23-25, 1903. The record of the students in this trial was given in THE JOURNAL, August 8.

Hereafter, as space will permit, we shall occasionally publish the questions of different state examining boards.

ANATOMY.

1. Describe the clavicle and scapula. 2. Describe the sacrum and coccyx. 3. Describe and illustrate the different classes of articulations. 4. Describe the hip joint, its ligaments and its synovial membrane. 5. Name and give origin of the muscles of the posterior tibial region (superficial group). 6. Name and give origin of the muscle of the anterior scapular region. 7. Give the origin and distribution of the ulnar artery. 8. Describe the deep veins of the lower extremity. 9. Describe the cecum. 10. Describe the pleura.

PHYSICAL DIAGNOSIS.

1. Give the signs of aortic valvular obstruction, with hypertrophy of the left ventricle. 2. How determine whether a cardiac murmur occurs with the first or second sound of the heart? 3. Differentiate between a pleuritic and a pericardial friction sound. 4. Differentiate between a pericardial effusion and a pleural effusion on the left side. 5. By what signs may ascites arising from disease of the kidneys be distinguished from that due to disease of the heart or liver? 6. Differentiate paralysis of the facial nerve due to a central lesion from one due to a peripheral lesion. 7. Make a differential diagnosis of tumor of the right kidney from tumor of the liver. 8. What would you elicit in an examination of the chest of a patient with advanced phthisis? 9. What are the signs of a dilated stomach? 10. Give the normal boundaries of the liver.

CHEMISTRY.

1. Define chemical incompatibility and give example. 2. Give chemical formula of three acids. 3. Describe "K" and its principal salts. 4. How is a salt formed? 5. Describe "Na" and its principal salts. 6. Differentiate organic and inorganic chemistry and give an example of each. 7. Explain the difference between a carbonate and a bicarbonate. 8. Give formulas and describe calomel and bichlorid. 9. Give tests for acids and alkalies. 10. Give tests for arsenic.

MATERIA MEDICA.

1. Creosote—from what is it obtained? What is its physiologic action? 2. What are the indications for creosote, its doses, and how is it administered? 3. Ipecac—physiologic action, indications and doses. 4. Chloral hydrate—physiologic action, indications and doses. 5. Phenacetin—physiologic action, indications, doses and uses. 6. Oxygen—in what condition and how is it used? 7. Serum therapy—on what scientific principle is it based? 8. Antidiphtheritic serum—how is it obtained and how used? 9. Anesthetics—mention those most generally used, and what are the dangers attending their use? 10. Local anesthesia—how is it produced?

PHYSIOLOGY.

1. In what do physiology and pathology differ? 2. How are the functions of the body classified? 3. Define the digestive process. 4. Describe the portal circulation. 5. What is chyle and how does it differ from lymph? 6. What is the coloring matter of the blood and its function? 7. How does the pneumogastric nerve influence the heart beat? 8. How is the temperature of the body kept at the standard? 9. What are the functions of the skin? 10. State the functions of the first two cranial nerves.

OBSTETRICS.

1. Define natural labor. 2. What precautions should be taken before and during the first examination in labor? 3. How would you manage a case of prolapsed cord? 4. What is dry labor and what are its difficulties and dangers? 5. How would you diagnose and manage a case of placenta previa? 6. Under what circumstances would you use a douche after labor or during the lying-in? 7. Define and describe involution. 8. What are some of the causes of mastitis? How should it be treated? 9. When should the cord be cut, and how dressed? Describe the process. 10. What should be done with a child prematurely born?

SURGERY.

1. Describe the application of the plaster-of-paris jacket. 2. How should fracture of the olecranon be treated? 3. Give causes and symptoms of adenitis. 4. What is saline transfusion and how is it performed? 5. What is asepsis and how would you secure it? 6. Describe the Trendelenburg position and its uses. 7. How would you treat a penerating gunshot wound of the abdomen? 8. How is suprapubic lithotomy performed? 9. What is the difference between true and false ankylosis? 10. What do you understand by intubation, and under what circumstances is it of use?

GYNECOLOGY.

1. Give symptoms, diagnosis, prognosis and treatment of acute metritis. 2. What is chronic endometritis, its causes and treatment? 3. Give etiology, symptoms and diagnosis of carcinoma uteri. 4. Give differential diagnosis of abdominal ascites and large ovarian cysts. 5. Give palliative treatment of retroversion of uterus.

DISEASES OF CHILDREN.

1. Differentiate between varicella and smallpox. 2. Give the technic of vaccination. 3. Differentiate enterocolitis from cholera infantum. 4. Differentiate catarrhal from lobar pneumonia. 5. Symptoms of hydrocephalus.

PRACTICE AND PATHOLOGY.

1. Give four causes of a persistent polyuria, and the results of a urinary examination. 2. Differentiate between gastralgia, gastric ulcer and gastric carcinoma. 3. Outline management of a case of organic cardiac lesion, with lost or broken compensation. 4. Describe the lesion and location in tabes dorsalis, and the signs by which the disease may be recognized. 5. What is ascites? Give causes, differential diagnosis and treatment. 6. What is cystitis? Give symptoms, diagnosis and treatment. 7. How diagnose and treat a case of diphtheria? 8. What does the word dysentery mean? Give symptoms and diagnosis of a case? 9. What do you understand by the terms symptoms, signs and periods of incubation and prodromes of disease? 10. Define erysipelas. Describe its course and give indications for three remedies.

Medical Organization.

Floyd County (Iowa) Medical Society.

Twelve physicians met at Charles City, July 24, and took preliminary steps toward reorganizing along the lines suggested by the American Medical Association. Dr. Semun R. Hewett acted as chairman and Dr. James J. Daly, as secretary, both of Charles City.

Audubon County (Iowa) Medical Society.

The physicians of Audubon County met in Audubon, July 21, organized a county medical society, adopted the constitution and by-laws recommended by the American Medical Association, and elected the following officers: Dr. H. P. Lauritzen, Exira, president; Dr. Ratford F. Childs, Audubon, vice-president; Dr. Daniel Jackson, Audubon, secretary-treasurer, and Drs. A. L. Brooks, Audubon, Nathaniel L. A. K. Slamberg, Kimballton, and Daniel G. Loss, censors.

Waupaca County (Wis.) Medical Society.

Physicians of Waupaca County met at Waupaca, July 28, with Dr. John F. Pritchard, Manitowoc, councilor for the Eighth District, and organized a county society to be in affiliation with the State and National organizations. The following officers were elected: Dr. Levi H. Pelton, Waupaca, president; Dr. Thomas W. Trimble, Waupaca, vice-president; Dr. J. Fremont Corbett, Weyauwega, secretary-treasurer, and Drs. Bruno G. Jurgensohn, Manawa, J. Fremont Corbett, Weyauwega, and Carl A. Sander, Waupaca, censors.

MEDICAL SCHOOLS OF THE UNITED STATES.

Below is given a brief description of every college in the United States that is legally chartered to confer the degree of doctor of medicine, and whose diploma is recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The information given is, as a rule, obtained from the catalogues and has been submitted to the dean of each school for his inspection and approval. Colleges which belong to the American or the Southern Medical College Association or other organization of colleges have requirements for admission of students according to the rules of these associations, unless their requirements are higher, in which case a statement is made to that effect. Extracts from these rules are given at the close of the list of colleges.

ALABAMA.

Alabama, population 1,828, 697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College, located in Mobile and in Birmingham. The population of each city is over 38,000 and board and room may be obtained for from $12 to $20 per month.

Mobile.

MEDICAL COLLEGE OF ALABAMA.—This is the Medical Department of the University of Alabama, organized in 1859. The City Hospital furnishes free clinical material. The faculty consists of 9 professors and 9 lecturers, 18 in all. It is well equipped with buildings, laboratories, dispensary, etc. It is a member of the Southern Medical College Association. The course of study covers four years of six months each. The total fees for each of the first three years is $100; for the fourth year, $125. The Dean is Dr. George E. Ketchum. Total registration, 1902-3, 145; graduates, 12. The thirty-eighth session will begin Oct. 8, 1903, and will close April, 1904.

Birmingham.

BIRMINGHAM MEDICAL COLLEGE.—This school was incorporated in 1894 and is situated in Birmingham, a manufacturing town of 38,415. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The laboratories are well equipped. There are 19 professors and 13 assistants, total, 32. The school is a member of the Southern Medical College Association. The course of instruction embraces four separate sessions of six months each. The fees are $75 for each of the first three years and $105 for the fourth. The Dean is Dr. B. L. Wyman. Registration, 1902-3, 94; graduates, 22. Next session opens Oct. 1, 1903, and closes April 1, 1904.

ARKANSAS.

Arkansas, population 1,311,564, has one medical college, located in Little Rock. Board and lodging costs from $13 to $18 per month.

Little Rock.

MEDICAL DEPARTMENT OF THE ARKANSAS UNIVERSITY.—This college is located at Little Rock, population about 60,000. It was organized in 1880 as the Arkansas Industrial University Medical Department. It is a charter member of the Association of American Medical Colleges. Hospital facilities are furnished by Logan H. Roots Memorial Hospital, St. Vincent's Infirmary and Pulaski County Hospital, the latter having a capacity of 200 beds. The teaching body consists of 13 professors and 23 lecturers and assistants, total 36. Dr. F. L. French, Little Rock, is Secretary. The fees are: Matriculation $5, paid but once; annual fees $60, and graduation $25. Total number of students at last session, 236; graduates, 12. The next course of lectures begins Oct. 19, 1903, and ends April 19, 1904.

CALIFORNIA.

California, population 1,485,053, has seven medical colleges. Five are located in San Francisco, a city of about 400,000 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Medical College of the Pacific, and the College of Physicians and Surgeons. The clinical facilities of San Francisco are good; board and lodging can be obtained for from $20 to $30 a month. The College of Medicine of the University of Southern California is situated in Los Angeles, population 102,479. Board and lodging can be obtained in that city for $4 a week and upward. The Oakland College of Medicine and Surgery is in Oakland, a suburb of San Francisco.

San Francisco.

COOPER MEDICAL COLLEGE.—This school was organized in 1858. though its present name was not adopted until 1882. The faculty consists of 12 professors and 28 lecturers, instructors, etc., 40 in all. Lane Hospital, adjoining the college, the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The requirements for admission are a certificate showing that applicant has passed the regular examination for admission to the University of California, or its equivalent, or graduation from an accredited high school or academy, or its equivalent. The college itself does not hold entrance examinations. The college building supplies large laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight months each. Fees: Matriculation, $5; course fee for each year, $150; breakage deposit each year, $10; graduation fee, $25; no other charges. The Dean is Dr. Henry Gibbons, Jr. Total registration for 1902-3 was 212; graduates, 45. The next session opens Aug. 15, 1903, and will close April 26, 1904.

MEDICAL DEPARTMENT UNIVERSITY OF CALIFORNIA.—This department of the State University was organized in 1872, and has a faculty composed of 20 professors, 50 associates and assistants, a total of 70. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The course covers graded work for four years of nine months each. This school is a member of the Associatioon of American Medical Colleges. In 1905 two full college years' work will be required of all applicants for admission. The fees are: Matriculation, $5; tuition, $150 each year; laboratory fees extra. The Dean is Dr. Arnold A. D'Ancona. Total registration for 1902-3 was 115; graduates, 26. The thirty-first session opens Aug. 7, 1903, and will close May 14, 1904.

COLLEGE OF PHYSICIANS AND SURGEONS OF SAN FRANCISCO.—This school was organized in 1896 and has a faculty of 23 professors and 23 associate professors and teachers, a total of 46. The hospital facilities consist of the City and County Hospital, the California General Hospital, with 50 beds, and St. Winifred Hospital, with 50 beds. The daily clinics at the new college building furnish abundant material of every description. Applicants for matriculation must show an equal amount of work done or pass a satisfactory examination in English, history and government, geography, physics, mathematics and Latin, grammar and translation. The college building recently completed is well supplied with laboratories and lecture rooms. This college now conducts a continuous course of medical instruction. Each year is divided into four quarters of three months each, and known as the autumn, winter, spring and summer quarters. Students may enter at the beginning of any quarter. Attendance on 12 quarters will be required, and at least 45 months must elapse between the beginning of the first course and the time of graduation. Fees, $30 per quarter. The Dean is Dr. D. A. Hodghead. Registration for 1902-3 was 146, of these 28 graduated in medicine. The autumn quarter opens Sept. 1, 1903, and closes May, 1904.

CALIFORNIA MEDICAL COLLEGE.—Eclectic. This school was organized in 1878. Its faculty includes 14 professors and 14 lecturers and instructors, a total of 28. The clinical material is supplied by the Buena Vista and City and County hospitals. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. Maclean. Total registration for 1902-3 was 60; graduates, 7.

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC.—Homeopathic. This was organized in 1884, and has a faculty of 19 professors and 23 lecturers, instructors, etc., in all 42. The Pacific Homeopathic Polyclinic, the Homeopathic Sanatorium, the San Francisco Nursery for Homeless Children, Marie Kip Orphanage, accommodating, respectively, 45, 75 and 120 beds; Fabiola Hospital and the City and County Hospital, furnish the clinical material for study. Matriculants must possess the equivalent of a high school education. One year after entrance is permitted in which the student may complete conditions in Latin. The college is registered and accredited with New York State Regents. The course includes four years of seven months each. Total fees for the first year, $155, and $100 for each of the other three years. The Dean is Dr. James W. Ward. Total registration for 1902-3 was 38; graduates, 12. The twenty-first session opened March 6, 1903, and will close Oct. 31, 1903.

Oakland.

OAKLAND COLLEGE OF MEDICINE AND SURGERY.—The second session of this new school will begin Sept. 1, 1903, and end April 30, 1904. The Registrar is Dr. Edward N. Ewer. The faculty numbers 21. Tuition is about $115 yearly. There were 6 students last session, all in the freshman class.

Los Angeles.

COLLEGE OF MEDICINE, UNIVERSITY OF SOUTHERN CALIFORNIA.—This school was organized in 1885, and has a faculty of 27 professors and 7 instructors, etc., 34 in all. The County Hospital, having 200 beds, and a college dispensary furnish clinical material. Applicants for admission are required to pass an examination in English, arithmetic, elementary algebra, physics and Latin equal to one year's work, unless they can show by certificate that they have covered that ground. The building is amply provided with laboratories and lecture rooms. A graded course, covering four years of thirty-two weeks each, is offered. The total fees for the first year are $145; second and third, $130 each, and $40 for the fourth year. The Dean is Dr. James H. McBride. Total registration for 1902-3 was 106; graduates, 27. The next session opens October, 1903, and closes June, 1904.

COLORADO.

Colorado, with a population of 539,700, has three medical colleges. Two of these, Denver and Gross College of Medicine and Denver Homeopathic College, are in Denver, which has a population of about 175,000, the other, the Colorado School of Medicine, is at Boulder (population 6,150). The clinical facilities in Denver available to the two colleges are the Arapahoe County Hospital, which has a capacity of 225 beds; St. Joseph's

Hospital, with 200 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upward.

Denver.

The Denver and Gross College of Medicine.—This is the Medical Department of the University of Denver, and was organized in 1902 by the union of the Gross Medical College (organized 1887) and the Denver College of Medicine (organized 1880). The clinical advantages are the college dispensary, the Arapahoe County Hospital, St. Luke's Hospital, St. Anthony's Hospital, St. Joseph's Hospital, National Jewish Hospital for Consumptives, Home for Dependent Children and the City Contagious Hospital and Mercy Sanitarium. The faculty is made up of 38 professors, 45 assistants and instructors, a total of 83. Its location is central and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months. The college is a member of the Association of American Medical Colleges. Final examinations at the end of each year are held. Fees for the first year are $115. For the second year $116. Third year $101. Fourth year $126. Total registration, 1902-3, 130; graduates, 33. The twenty-third session will begin Sept. 15, 1903, and close May 16, 1904. The Dean is Dr. S. G. Bonney.

Denver Homeopathic College.—This college, organized in 1894, beside clinical privileges in the Arapahoe County Hospital, has exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven and the Belle Lenox Nursery. The faculty numbers 25 professors and 7 lecturers and instructors, 32 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first-grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of seven months each; monthly examinations are held in each subject. A five-year scholarship may be had for $300, payable in advance, otherwise the tuition is $100 a year; there is a matriculation fee of $5, payable once. The Dean is Dr. James P. Willard. Total registration for 1902-3 was 29; the number of graduates. 6. The ninth session begins in September, 1903, and will close April, 1904.

Boulder.

Colorado School of Medicine.—This is the Medical Department of the University of Colorado, and was opened in 1883. The University Hospital, under the control of the state, is equipped to accommodate 40 patients and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located in Boulder offers additional advantages in this line. The faculty embraces 15 professors and 12 lecturers and assistants, a total of 27. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Giffin. Total registration for 1902-3 was 63; graduates, 8. The twenty-second session begins Sept. 14, 1903, and closes June. 1904.

CONNECTICUT.

Connecticut has a population of 908,420, and contains one medical college, located in New Haven, population 115,000. Board and lodging cost $4.50 and upward per week.

New Haven.

Yale Medical School.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which, from the granting of the first charter, had taken an active part in its control, released itself from a further responsibility and the University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 150 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, which, with its 1,800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Besides these, the University has just completed a $100,000 building for the dispensary service, which offers good material for clinical teaching. The faculty embraces 13 professors, 5 lecturers, 12 instructors, and 22 assistants, a total of 52. The lecture rooms and laboratories are large and well equipped. Matriculants are admitted without examination, provided that they have received a degree in arts or sciences, that they present certificates showing that they have successfully prosecuted the subjects of the examination at some college, high school, academy, or preparatory school approved by the faculty, or that they have passed matriculation examinations equivalent to those required, at some approved professional school. This school is a member of the Association of American Medical Colleges. The course covers a four-year graded curriculum, eight months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 each year; in the first year there are additional fees amounting to $18, and in the second, $8, and there is a graduation fee of $10. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1902-3 there were 145 matriculants and 27 graduates. The ninety-first session opens Sept. 24, 1903, and closes June 23, 1904.

DISTRICT OF COLUMBIA.

Washington, population, 278,718, has four medical colleges: Medical Department of Columbian University, Georgetown University School of Medicine, Howard University Medical Department and National University Medical Department. Washington offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, the library in the Surgeon-General's office, the Toner Medical Library and Museum of Hygiene, in all over 125,000 volumes on medicine, open to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at extremely reasonable rates.

Washington.

Columbian University, Department of Medicine.—This school was organized in 1821. Columbian University Hospital, under the immediate control of the faculty, gives the students of this school exclusive clinical advantages. In addition, Central Dispensary and Emergency Hospital, Lutheran Eye and Ear Infirmary, Episcopal, Garfield, Children's, Providence, Columbia and St. Elizabeth's hospitals, all permit of abundant opportunity for clinics and clinical material. The faculty is composed of 26 professors and 30 demonstrators and assistants, 56 in all. This school is a member of the Association of American Medical Colleges. The equipment and facilities for laboratory, didactic and clinical work are good. The completion of graded work covering the period of four years, eight months to the school year, is required; semi-annual examinations are held. Total fees for each year are $110. The Dean is Dr. E. A. de Schweinitz, 1325 H St., N. W. New and enlarged buildings for both college and hospital have been completed. Registration for 1902-3 was 260; graduates, 34. The eighty-second session begins Sept. 30, 1903, and closes June 1, 1904.

Georgetown University School of Medicine.—This school, organized in 1850, controls the Georgetown University Hospital, which affords excellent facilities for clinical teaching and ward classes. Clinics are also held for the benefit of the students in Providence Hospital, containing 300 beds; in the Children's Hospital, the Central Dispensary, Emergency Hospital and the Garfield Hospital. Attendance on clinical instruction is obligatory in the third and fourth years. The faculty contains 26 professors, 27 instructors and assistants, total 53. This school is a member of the Association of American Medical Colleges. The building is conveniently located and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight months each. Examinations are held at the end of each session. The fees are $110 each year. The Dean is Dr. George M. Kober, 1600 T St. The registration for 1902-3 was 144; graduates, 22. The next term opens on Sept. 29, 1903, and ends May 31, 1904.

Howard University Medical Department.—This institution was organized in 1867 and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, who compose a majority of those in attendance, but a number of white students are also receiving instruction. The Freedman's Hospital and Asylum is a general hospital of 300 beds. The faculty comprises 15 professors and 20 lecturers and assistants, 35 in all. This college is a member of the Association of American Medical Colleges. Students are required to attend four courses of lectures in separate years of seven months each. The fees of each session are $80, plus $2 per part for dissecting material. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 714 13th St. N. W. Registration for 1902-3 was 141; graduates, 29. The thirty-sixth session begins Oct. 1, 1903, and closes May, 1904.

National University Medical Department.—We are unable to furnish information concerning this school, as repeated letters to different officials have failed to elicit any reply. In our statistical table we use the same figures as were used last year, assuming that they are approximately correct. The school was organized in 1884 and has a faculty of about 37. The course consists of four years of eight months each.

GEORGIA.

Georgia, population 2,216,331, has three medical colleges: Medical College of Georgia, located in Augusta (population, 39,441); Atlanta College of Physicians and Surgeons, and Georgia College of Eclectic Medicine and Surgery, both in Atlanta (a manufacturing city of 89,872 population). Board and lodging may be obtained for from $3 to $5 per week.

Augusta.

Medical College of Georgia.—This school was organized as a medical academy in 1829, and in 1873 was made the Medical Department of the University of Georgia. Its faculty includes 12 professors and 12 assistants, 24 in all. The course is four years of six months each. Applicants for admission must, by examination, certificate or diploma, show that they possess educational qualifications equal to those required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted, and they may remove the conditions any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80 beds; the Polyclinic and the Hospital for Contagious Diseases supply clinical material. Fees for the first two years are $75 each; third year, $100, and 130 for the last year. The Dean is Dr. DeSaussure Ford. Total enrolment for 1902-3 was 110; graduates, 7. The seventy-second session opens Oct. 1, 1903, and closes April, 1904.

Atlanta.

Georgia College of Eclectic Medicine and Surgery.—This was organized in 1839, and has a faculty of 12. The college dispensary and Grady Hospital furnish clinical material. Applicants for admission must adhere to the requirements established by the

National Confederation of Eclectic Colleges of which this college is a member. The curriculum covers four years of six months each. The Proctor is Dr. W. M. Durham, 77½ Peachtree St. Total number of students for 1902-3 was 46; graduates, 2. The next session opens Oct. 1, 1903, and closes April 1, 1904.

ATLANTA COLLEGE OF PHYSICIANS AND SURGEONS.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It has a faculty of 14 professors and 20 assistants, a total of 28. Clinical facilities are furnished by the Grady Hospital, which is the general hospital for Atlanta; clinics are free to the graduating class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." The course of study covers four years of six months each and is graded. The buildings are large and a new building for practical anatomy has just been added. Fees: First and second years, $75 each; third and fourth, $100 each. The Dean is Dr. W. S. Kendrick, 71 Washington St. Total registration of students for 1902-3 was 200; graduates, 34. Next session begins Oct. 1, 1903, and closes April, 1904.

ILLINOIS.

Illinois, population 4,821,550, has 14 medical colleges. They are all located in Chicago, a city of about 1,900,000 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, Chicago Homeopathic Medical College, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Harvey Medical College, Illinois Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University and American College of Medicine and Surgery. Room and board cost $3 a week and upward.

Colleges in Illinois have to admit students in conformity with the minimum requirements of the Illinois State Board of Health, as follows: "A diploma or certificate of graduation from a high school; or a certificate signed by a principal of a regularly organized high school or by the examiner of the faculty of a recognized literary or scientific college or university, or by the state superintendent of public instruction, or a superintendent of public schools, of having successfully passed an examination in all the several branches embraced in the curriculum of a four years' high school course. The matriculation examination shall not be conducted by any member of the faculty of the medical college. The Illinois State Board of Health will require each applicant for a state certificate to present documentary evidence of his preliminary education, together with his medical diploma, when taking the examination of the board." These conditions will govern all persons admitted to the freshman year on or after Jan. 1, 1903.

Chicago.

RUSH MEDICAL COLLEGE.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 to 1898, and in the latter year became affiliated with the University of Chicago. The faculty is composed of 22 professors, 144 associates, instructors, etc., a total of 166. Good clinical facilities are furnished by Cook County Hospital, caring for about 20,000 patients yearly; Presbyterian Hospital, with 250 beds; a college dispensary, and an obstetric department. In addition to these, extramural clinical courses are offered at the West Side Hebrew Dispensary, St. Luke's Hospital, St. Anthony's Hospital, the Alexian Brothers' Hospital, Illinois Charitable Eye and Ear Infirmary and Chicago Isolation Hospital. Bedside instruction is given. The requirements for admission are those of admission to the better universities or colleges and, in addition thereto, one and one-third years of college work. For the sessions of 1904 there will be required a certificate of admission to the third academic year of an accredited university. By the addition of a recently completed seven-story building, the facilities for clinical instructions are largely increased. The laboratories and their equipment are unexcelled. The curriculum covers graded work for four years of three quarters each, a quarter being three months. A continuous session is held, but credit for more than three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both science and medicine. All freshmen and sophomore studies are given at the University of Chicago. The total regular fees are $172.50 this year, but it is designed to gradually increase the fees to $200 per year. However, students in continuous attendance, i. e., three quarters in twelve months, may complete their course by paying the fees in vogue when they first enter the college. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Deans are Dr. Frank Billings, 100 State St., and Dr. John M. Dodson, 34 Washington St. Total registration, 1902-3, was 1,047; graduates, 220. The fiscal year begins July 1; final examinations are held at the end of each year.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL.—This school was organized in 1859 as the Medical Department of Lind University, became independent as the Chicago Medical College in 1864, and in 1869 assumed its present relation as Medical Department of Northwestern University. The faculty comprises 41 professors and 67 assistants and instructors, in all, 108. The newly completed Wesley Hospital, with 225 beds; Mercy Hospital, containing 400 beds; Provident Hospital, 100 beds; St. Luke's, 200 beds, and a college free dispensary furnish opportunities for clinical study to students of this college exclusively. Cook County, and the Chicago Lying-in hospitals are also open to them for study. Applicants for admission must, by diploma, certificate or examination, show possession of the educational acquirements required to enter the College of Liberal Arts of Northwestern University. This school is a member of the Association of American Medical Colleges. The laboratory and lecture-room facilities are ample and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Optional summer laboratory and clinical courses are also given. Final examinations are held at the end of each semester. The fees for each year are $165 and a matriculation fee of $5, paid once, is charged. The Dean is Dr. N. S. Davis, Jr., 65 Randolph St. The total registration for 1902-3 was 608; graduates, 127. The next session opens October, 1903, and closes June, 1904.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1881, and in 1896 became the Medical Department of the University of Illinois. The faculty is composed of 43 professors, 90 assistants and instructors, a total of 133. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and maternity clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the following hospitals for clinical study: Augustana, Baptist, Chicago, Woman's, Samaritan, Alexian Brothers', St. Mary's, and the Chicago Lying-in. This school is a member of the Association of American Medical Colleges. A magnificent building has recently been added to the college, and the laboratory, amphitheater and lecture-room space and equipment are excellent. The collegiate year is divided into two terms: the winter term of thirty-two weeks and the summer term of twelve weeks, of actual teaching. Attendance on the winter term is required in order to secure credit for a year's work, and attendance on four winter terms is required for graduation, except for students who are admitted to advanced standing. Attendance on the summer term is optional, and the work is supplementary to the work of the winter term. Students may obtain credit for work done in certain branches, but attendance on this term does not apply on the required thirty-two months' attendance necessary for graduation. The fees are $145 each for the first two years, $130 for the third and $155 for the fourth year. The Dean is Dr. William E. Quine, 103 State St. Total registration for 1902-3 was 685; graduates, 216. The fall term begins Oct. 1, 1903.

HAHNEMANN MEDICAL COLLEGE.—Homeopathic. This was organized in 1855, and has a faculty of 60. Hahnemann Hospital and a college dispensary supply clinical material. The requirements for admission are a high school diploma or its equivalent. The course is four years of seven months each. Fees: Matriculation, paid once, $5; each term, $50, and hospital tickets, $5 each for third and fourth years. The Registrar is Dr. W. Henry Wilson. Total registration, 1902-3, 195; graduates, 69. The next session begins Sept. 27, 1903.

BENNETT COLLEGE OF ECLECTIC MEDICINE AND SURGERY.—This school, organized in 1868, has a faculty of 32 professors and 5 assistants, 37 in all. The Bennett, Cook County and Baptist hospitals and a college dispensary supply clinical facilities. Matriculants must present a diploma or certificate or pass a satisfactory examination "in conformity with the minimum requirements of the State Board of Health." The course covers four years of twenty-six weeks each. This school is a member of the National Confederation of Eclectic Medical Colleges. Fees for each year are $100, with a matriculation fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1902-3, was 113; graduates, 18. The thirty-sixth session begins Sept. 22, 1903, and ends May 11, 1904.

CHICAGO HOMEOPATHIC MEDICAL COLLEGE.—This was organized in 1876, and has a faculty of 19 professors and 44 adjuncts, lecturers, etc., a total of 63. The Chicago Homeopathic and Cook County hospitals, together with a college dispensary, furnish clinical material. Applicants for admission must show by certificate from high school, or its equivalent, a sufficient knowledge of English, arithmetic, algebra, physics, United States history, geography, botany and Latin, equivalent to a year's study. The course covers four years of seven and one-half months each. Total fees are about $110 for each year. The Dean is Dr. W. M. Stearns, 87 Wabash Ave. Total registration, 1902-3, was 130; graduates, 37. The next session opens September, 1903, and ends April, 1904.

HERING MEDICAL COLLEGE.—Homeopathic. This school was organized in 1892. Dunham Medical College, organized in 1895, was consolidated with this school in August, 1902. The faculty comprises 28 professors and 16 associates, lecturers, etc., in all 44. Hering College Hospital, Baptist and Cook County hospitals supply clinical facilities. The course covers four years of seven months each. The total fees for a full course are $300 if paid in advance, or $100 per year. The Dean is Dr. J. T. Kent, 92 State St. Total registration for 1902-3 was 90; graduates, 22. The twelfth session begins Sept. 8, 1903, and ends April 11, 1904.

JENNER MEDICAL COLLEGE.—This is a day and evening school, organized in 1892. The faculty consists of 46 professors and 7 assistants, 53 in all. Cook County Hospital and college dispensary supply clinical material. The course covers four years of 40 weeks each and embraces laboratory, didactic and clinical instruction. The total fees each year are $100, with a $5 matriculation fee, paid but once. The Registrar is Dr. C. Shorman, 163 Randolph St. Total enrolment for 1902-3 was 107; graduates, 13. The next session begins September, 1903, and will end June, 1904.

HARVEY MEDICAL COLLEGE.—This is a night school, organized in 1891. The lecture and laboratory work is all in the evening between the hours of 7 and 10, six days of the week and forty weeks of the year. The clinical work, hospital, dispensary, in-practice and out-practice, are between the hours of 10 a. m. and 10 p. m. Attendance on 100 clinical hours yearly before 7 in the evening is obligatory beside attendance by the seniors on night obstetric cases and Saturday evening clinic at Cook County Hospital. The faculty is composed of 42 professors, 21 instructors and assistants, total, 63. The course covers four years of ten months each. The total fees are, each year, $200. The Dean is Dr. Frances Dickinson. Total registration for 1902-3 was 330;

graduates, 20. The thirteenth session begins September, 1903, and ends June, 1904.

Illinois Medical College.—This school, organized in 1894, has a faculty of 26 professors and 19 assistants, a total of 45. A college dispensary and Cook County Hospital are available for clinical study. The requirements of admission include a high school diploma or its equivalent. The college is a member of the Association of American Medical Colleges. Attendance for seven months during each of four years is necessary for graduation. Total fees are about $75 for each year. The Dean is Dr. B. B. Eads, 103 State St. Total registration for 1902-3 was 265; graduates, 47. The next fall term begins Oct. 1, 1903.

American Medical Missionary College.—This school was organized in 1895 and has the primal object of educating men and women as missionary physicians. The faculty numbers 25. The didactics and laboratory work, covering the first two years, are carried on at Battle Creek, Mich., and the clinical studies in Chicago. A hospital with 20 beds, in connection with the college, together with a free college dispensary, with an obstetric department, supply material for practical work. The college is a member of the Association of American Medical Colleges. The course covers four years of nine months each. Total fees are $125 for each of the four years. The Secretary is Dr. E. L. Eggleston, Battle Creek, Mich. Total registration for 1902-3 was 88; graduates, 22. The ninth session opens Sept. 23, 1903, and closes June 22, 1904.

College of Medicine and Surgery.—Physio-Medical. This school was organized in 1896 and has a faculty of 44 teachers. A college dispensary supplies material for clinical work. The course covers four years of seven months each. Fees for the first year, $100; for the second and third, $95 each, and $110 for the fourth. The Secretary is Dr. Florence Dressler, 245 Ashland Boul. Total registration for 1902-3 was 76; graduates, 12. The next session begins September, 1903, and ends April, 1904.

National Medical University.—This was organized in 1891, and its courses include instruction in the methods of all the so-called schools of practice, including osteopathy. The faculty numbers 76. The requirements for entrance are in accordance with the requirements of the Illinois State Board of Health. Each year is divided into four quarters of thirteen weeks each. The fees are $100 per year. The Registrar is Dr. L. D. Rogers, 533 Wells St. Total matriculants for 1902-3 were 173; graduates, 17. The autumn quarter will begin Sept. 30, 1903.

American College of Medicine and Surgery.—Eclectic. This school was founded in 1901 and has a faculty of 65. The requirements for entrance are in accord with the rules of the State Board of Health. The course is four years of eight months each. American and Cook County hospitals supply clinical material. The Secretary is Dr. J. D. Robertson, 103 State St. The annual fee is $100; matriculation fee is $5; a total fee for one year, with board, room, light and heat, is $208. The enrolment, 1902-3, was 126; graduates, 10. The next session begins Sept. 29, 1903, and closes May 14, 1904.

INDIANA.

Indiana, population 2,516,462, has five medical colleges. Four are situated in Indianapolis, a city of 169,164 people: The Central College of Physicians and Surgeons, Medical College of Indiana, the Eclectic Medical College and the Physio-Medical College of Indiana. The clinical facilities of Indianapolis are good, and board and lodging can be obtained from $3 a week and upward. The Fort Wayne College of Medicine is situated in Fort Wayne, a railroad and manufacturing town of 45,115 inhabitants. Board and room can be obtained there at an average of $3 a week.

Indianapolis.

Central College of Physicians and Surgeons.—This school was organized in 1879 and reorganized in 1901. The faculty numbers 23 professors and 45 lecturers and demonstrators, total 68. A new college building has been erected on the most up-to-date plans. Its floor space comprises 25,000 square feet, more than half of which is devoted to laboratory teaching. The school gives instruction largely by laboratory and clinical methods. Clinical facilities are furnished by a dispensary maintained by the college, by the City Dispensary, City Hospital, St. Vincent's Infirmary and the Central Hospital for the Insane. Bedside clinics are given to sections of senior class daily at City Hospital. This college was a charter member of the Association of American Medical Colleges. The course is four years of 7 months each. The Secretary is Dr. John F. Barnhill. The fees are $75 for each year. Total registration, 1902-3, was 115; graduates, 22. The session for 1903-4 will open Sept. 22, 1903.

Medical College of Indiana.—This is the Medical Department of the University of Indianapolis and was organized in 1869. The faculty embraces 26 professors, 42 adjuncts, lecturers, etc., a total of 68. The City Hospital, containing 200 beds; Indianapolis Dispensary; Central Hospital for the Insane, with a capacity for 1800 patients; St. Vincent's and the Maternity hospitals, and a college dispensary provide clinical facilities; the wards in the charity hospitals are open to students of this college for bedside instruction. The laboratory and lecture-room space is ample. This college is a member of the Association of American Medical Colleges. The course extends over four years of seven months each. Fees: First and second years, $80 each; third, $75, and $100 for the fourth year, which includes graduation fee. The Dean is Dr. Henry Jameson, Newton-Claypool Bldg. Total enrolment for 1902-3 was 332; graduates, 76. The thirty-fourth session opens September, 1903, and closes April, 1904.

Eclectic Medical College of Indiana.—This school was organized in 1900 and has a teaching force of 31. The course is four years of six months each. Fees: For each year, $75, or for all four, $225; $25 for graduation. Total registration, 1902-3, 28; graduates, 5. The Dean is Dr. R. T. Laycock, 909 Bates St. The next session begins Sept. 22, 1903, and ends April 10, 1904.

Physio-Medical College of Indiana.—This school was organized in 1873, and has a faculty of 30. The course is four years of 26 weeks each. Total fees for each year are $70. The Secretary is Dr. C. T. Bedford. Total enrolment, 1902-3, was 29; graduates, 9. The next session begins Oct. 7, 1903, and closes May, 1904.

Fort Wayne.

Fort Wayne College of Medicine.—This school was organized in 1879, has a faculty of 25 professors and 9 lecturers and assistants, a total of 34. St. Joseph's Hospital, with a capacity of 250 patients; Hope Hospital, with 200 beds; St. Roche's Hospital, having accommodation for 35 patients; Indiana School for Feeble-Minded Youth and Allen County Orphan Asylum, capable of holding 150 children, supply the clinical facilities. This school is a member of the Association of American Medical Colleges. The curriculum covers four years of seven months each. The course is practical, supplemented by lectures and laboratory work. The total fees for each year are $75, with an additional $5 matriculation fee, payable once. The Dean is Dr. C. B. Stemen, 715 Broadway. Total registration, 1902-3, was 46; graduates, 5. The next session opens Sept. 8, 1903, and closes April 22, 1904.

IOWA.

Iowa, population 2,231,853, contains five medical colleges. The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City (population 7,987). In Des Moines (population 62,139) is the Iowa College of Physicians and Surgeons. In Sioux City (population 33,111) is the Sioux City College of Medicine. In Keokuk (population 15,641) is Keokuk Medical College, College of Physicians and Surgeons. Board and lodging may be had in Des Moines for $15 a month and upward and in the other cities named for from $2.50 to $5 per week.

Iowa City.

College of Medicine of the State University of Iowa.—This department was organized in 1870. The faculty is made up of 13 professors, 26 lecturers, demonstrators and assistants, a total of 39. The University Hospital, built in 1897 at a cost of $50,000, supplies the clinical material. The school is a member of the Association of American Medical Colleges. The course of study covers four years of thirty-six weeks each, embracing graded laboratory, didactic and clinical work. Combined courses leading to more than one degree are offered. Total fees for each year are $65. The Dean is Dr. James R. Guthrie, Dubuque. Total number of students registered for 1902-3 was 251; graduates, 35. The thirty-fourth session opens Sept. 24, 1903, and ends June 15, 1904.

College of Homeopathic Medicine of the State University of Iowa.—This was organized in 1877. The faculty is composed of 10 professors and 10 lecturers and assistants, a total of 20, but some of these are of the faculty of the College of Medicine. The requirements for admission, and the work, with the exception of that pertaining to homeopathy, are the same as those for the other department. The fees are also the same. The Dean is Dr. George Royal, Des Moines. Total registration for 1902-3 was 35; graduates, 11. The twenty-seventh session begins in September, 1903, and will end in June, 1904.

Des Moines.

The Iowa College of Physicians and Surgeons.—This, the Medical Department of Drake University, was organized in 1882. The faculty contains 16 professors and 16 assistants, a total of 32. Mercy and Methodist hospitals furnish clinical material and attendance on clinics is required the same as on lectures. The requirements for admission are those determined by the Association of American Medical Colleges, of which association this college is a member, and by the Iowa State Board of Medical Examiners. Instruction is given by means of lectures, recitations, demonstrations, laboratory work and hospital clinics. The work covers a graded course of four years of nine months each. The total fees for the first two years are $80 each, and for the last two years, $75 each. The Dean is Dr. D. S. Fairchild. The total registration for 1902-3 was 66; graduates, 11. The twenty-second session begins Sept. 14, 1903, and ends June 16, 1904.

Sioux City.

Sioux City College of Medicine.—This school was organized in 1891. The faculty numbers 15. Clinical material is supplied by St. Joseph's, Mercy and Samaritan Hospitals and a college dispensary. This college is a member of the Association of American Medical Colleges. The system of study embraces a four year graded course, eight months being a school year. Final examinations are held at the close of each course of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fee, $5, and graduating fee, $20. The Secretary is Dr. J. N. Warren. Total number of students registered, 1902-3, was 72; graduates, 13. The fourteenth session opens Sept. 8, 1903, and will close May 4, 1904.

Keokuk.

Keokuk Medical College, College of Physicians and Surgeons.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized and four years later it became the Medical Department of the University of Iowa, continuing as such until 1870 when the original name was resumed. By the union, in 1899, of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. The clinical material is good. St. Joseph's Hospital is open to the student for study and the clinics held there are large and varied. The faculty is composed of 17 professors and 5 assistants and demonstrators, 22 in all. This college is a member of the Association of American Medical Colleges. The studies embrace a graded course of four years of seven months each. The total fees for the first year are $63; for the second and third, $58 each, and $53 for the last year. The Secretary is Dr. C. E. Ruth. Total registration for 1902-3 was 243; graduates, 56. The next session begins Sept. 15, 1903, and ends April 19, 1904.

KANSAS.

Kansas, population 1,470,495, has three medical colleges: Kansas Medical College is in Topeka (population 33,608), and the College of Physicians and Surgeons in Kansas City (population 55,000). In addition, there is a school which does not grant degrees, but prepares students in the first two years. This is the Medical School of the University of Kansas, at Lawrence, a town of 10,862 people. Board and lodging in all these places may be had for $3 to $5 per week.

Lawrence.

SCHOOL OF MEDICINE OF THE UNIVERSITY OF KANSAS.—This school does not confer the degree of Doctor of Medicine. It was organized in 1880. The faculty numbers 18. This school is a member of the Association of American Medical Colleges. Only the purely scientific subjects are taught, but the work in these is thorough, seventy-two weeks being devoted to the two-year course. The greater part of the work is in the laboratory, with recitations and assigned readings, the lectures being supplementary only. For this reason the equipment and arrangement of the laboratories have been given special attention. A combined course of four years is offered, conferring "the degree of bachelor of arts in medicine." The total fees to residents of the state are: First year, $35; second, $30; to non-residents of the state, $60 and $50. The Acting Dean is Dr. C. E. McClung. The number of students registered for 1902-3 was 31. The next session begins September, 1903, and will end June, 1904.

Topeka.

KANSAS MEDICAL COLLEGE.—This college, organized in 1890, has a faculty of 25 professors and 8 lecturers and assistants, 33 in all. Good material for both medical and surgical clinics is found in Christ's Hospital, with 100 beds, and Topeka State Hospital; the dispensary in the college building also supplies material for class demonstration. The college is a member of the Association of American Medical Colleges. The college building affords ample laboratory and lecture-room space. The course of study is a graded one covering four years of 30 weeks each. Individual instruction is especially aimed at. The total fees for the first three years are $70 each, and $30 for the last year. The Dean is Dr. John E. Minney. The total registration for 1902-3 was 101; graduates, 12. The fourteenth session begins Sept. 16, 1903, and will close April 14, 1904.

Kansas City (Kansas).

COLLEGE OF PHYSICIANS AND SURGEONS.—This was organized in 1894 as the Medical Department of Kansas City University. The faculty is made up of 29 professors, 13 lecturers and assistants, a total of 42. Bethany Hospital, with 60 beds; St. Margaret's Hospital, a college dispensary and an outside obstetric department supply clinical material. Practical demonstration and bedside teaching is emphasized in the work. The requirements for admission are in accordance with the rules of the Association of American Medical Colleges. The course of study is a graded one of four years, seven months each. A scholarship is offered for $175, but taken separately the total fees for the first three years are $60 each, and for the fourth year, $50; matriculation fee, $5, payable once. The Dean is Dr. J. W. May. The total registration of students for 1902-3 was 52; graduates, 10. The tenth session opens September, 1903, and will close March, 1904.

KENTUCKY.

Kentucky, population 2,147,174, has seven medical colleges. They are all situated in Louisville, a city of about 225,000 inhabitants, and are as follows: University of Louisville Medical Department, Kentucky School of Medicine, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department, and Louisville National Medical College. Board and lodging in Louisville cost from $3 to $4 per week.

Louisville.

UNIVERSITY OF LOUISVILLE MEDICAL DEPARTMENT.—This school was organized in 1837, under the name, Louisville Medical Institute, and in 1846 assumed its present title. It has a faculty of 11 professors, 26 lecturers, demonstrators, etc., a total of 37. The University Hospital, City Hospital, Sts. Mary and Elizabeth Hospital, together with the college dispensary, furnish good clinical material. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of six months each. There are two six months' courses in the year; one course runs from Sept. 21, 1903, to April 1, 1904; the other runs from Jan. 1, 1904, to July 1, 1904. Total fees: First year, $107; second, $122; third, $100, and fourth, $112. The Dean is Dr. J. M. Bodine. Total registration for 1902-3 was 227; graduates, 34. The sixty-seventh session begins Sept. 21, 1903.

KENTUCKY SCHOOL OF MEDICINE.—This school was organized in 1850, and has a faculty composed of 20 professors, 19 lecturers, instructors and assistants, a total of 39. The College Hospital, City Hospital and the college dispensary furnish the facilities for clinical study. The student is brought directly into contact with the patient through dispensary and bedside work by dividing the classes into sections. This college is a member of the Association of American Medical Colleges. The laboratories and their equipment are good. The curriculum embraces a four years' course of 28 weeks each. The fees for the first two years are $120 each; for the third year, $100, and $90 for the fourth year. The Dean is Dr. W. H. Wathen, 628½ Fourth Ave. Total number of students registered for 1902-3 was 290; graduates, 56. The next session begins Jan. 1, 1904, and will end July 15, 1904.

LOUISVILLE MEDICAL COLLEGE.—This school was organized in 1869 and has a faculty of 11 professors and 11 instructors and assistants, 22 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by diploma, certificate or examination that they are sufficiently proficient in English, arithmetic, algebra, physics and such Latin as would be acquired in one year's study. The laboratories and lecture rooms are ample. The course of study covers four years of six months each. The fees for the first three years are $100 each; for the fourth, $90. The Secretary is Dr. Irvin Abell. Total registration for 1902-3 was 257; graduates, 53. The next session opens Sept. 21, 1903, and closes March 31, 1904.

HOSPITAL COLLEGE OF MEDICINE.—This school is the medical department of Central University of Kentucky and was organized in 1873. The faculty is composed of 9 professors and 35 assistants, lecturers, etc., a total of 44. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities for clinical study. This college is a member of the Association of American Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of six months each. Total fees for each of first two years, $120; for the third year, $85, and $125 for the fourth year. The Dean is Dr. P. Richard Taylor. Total enrolment for 1902-3 was 421; graduates, 69. The thirtieth session opens Jan. 1, 1904, and closes July 1, 1904.

KENTUCKY UNIVERSITY MEDICAL DEPARTMENT.—This school was organized in 1898. The faculty is composed of 14 professors, 19 lecturers, demonstrators, etc., 33 in all. Broadway Infirmary, the City Hospital and a college dispensary furnish clinical material. The school is a member of the Association of American Medical Colleges. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work for four years of at least twenty-six weeks each. The calendar year is divided into four quarters of thirteen weeks each. Two quarters constitute a college year. Fees are $25 per quarter. The Dean is Dr. Thomas C. Evans, 419 W. Chestnut St. Total number of students registered in 1902-3 was 330; graduates, 57. The next session opens Oct. 1, 1903.

SOUTHWESTERN HOMEOPATHIC MEDICAL COLLEGE.—This college was organized in 1892 and has a faculty of 18 professors and 12 lecturers and assistants, 30 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven months each. Total fees: First and second years, $80; third, $70, and $65 for the fourth. The Dean is Dr. A. L. Monroe. Total number of students for 1902-3 was 22; graduates, 5. Next session opens Sept. 29, 1903, and closes April 26, 1904.

LOUISVILLE NATIONAL MEDICAL COLLEGE.—Colored. This was chartered in 1888 and shows a teaching force of 19. There is a four-year course, seven months to the year; the fees are $58, $58, $55 and $50 for the four years respectively. The Dean is Dr. W. A. Burney. The attendance, 1902-3, was 26; graduates, 4. The next session opens Oct. 6, 1903, and ends about May 10, 1904.

LOUISIANA.

Louisiana, having a population of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 287,104 people. The cost of room and board is from $16 to $22 a month.

New Orleans.

MEDICAL DEPARTMENT OF THE TULANE UNIVERSITY OF LOUISIANA.—This school was organized in 1834 as the Medical College of Louisiana, and became, by law, in 1847, the Medical Department of the University of Louisiana, and in 1884 the Medical Department of the Tulane University of Louisiana. The faculty and all other instructors number 41. By acts of legislature the Charity Hospital, with its 900 beds, has been opened to the students of this school for clinical study, not only in medicine and surgery, but also in obstetrics and gynecology. In the year 1902 there were 8,793 cases treated in the wards of this hospital; these were indoor patients, and, in addition, 21,129 outdoor patients were treated in the free dispensary department. The Milliken Memorial Hospital, with a capacity for 200 children, is also available for study of clinical cases. Bedside instruction is given by the attending physicians to these hospitals, and postmortem examinations are held before the students. This college is a member of the Southern Medical College Association. The laboratories are large and well equipped, and the lecture rooms and recitation rooms are ample. The course of study covers four years of twenty-eight weeks each. Total fees for the first two years are $135 each, and for the third and fourth, $145 and $165 respectively. The Dean is Dr. Stanford E. Chaille, New Orleans. The total number of medical students registered for 1902-3 was 405; graduates, 82. The seventieth session begins Oct. 22, 1903, and will close May 4, 1904.

FLINT MEDICAL COLLEGE OF NEW ORLEANS UNIVERSITY.—Colored. This school was organized in 1889. The faculty is made up of 9 professors, 4 lecturers and instructors, 13 in all. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. This college is a member of the Association of American Medical Colleges. The curriculum covers a graded course of four years, thirty weeks each. The laboratories and lecture rooms are ample. Examinations are held monthly. Total fees for the first, second and third year are $40 each, and $50 for the last year. The Dean is Dr. H. J. Clements, New Orleans. Total enrolment for 1902-3 was 42; graduates, 5. The fifteenth college year begins Sept. 1, 1903, and will end March 18, 1904.

MAINE.

Maine, population 694,466, has one medical college, located in Portland, population 50,000. Board and lodging cost from $3 to $5 a week.

Portland.

MEDICAL SCHOOL OF MAINE.—This, the Medical Department of Bowdoin College, was organized in 1820. It has 13 professors and 5 instructors, total 18. Students of the first and second years are instructed in Brunswick, a town with 6,800 inhabitants. The third

and fourth year classes are taught in Portland, where are situated the Maine General Hospital and other clinical advantages. Applicants for admission, unless they possess a diploma, are examined in English, arithmetic, algebra, geometry, United States history, physics, chemistry and Latin. The course covers four years of twenty-six weeks each. The total fees are $120 for the first year; for the second and third, $110, and $110 for the fourth year. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1903, 100; graduates, 20. The next session opens Dec. 23, 1903, and closes June 23, 1904.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges, all located in Baltimore, a city with 508,957 inhabitants. They are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Woman's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School and Maryland Medical College. The Bay View Hospital, having a capacity for 2,000 patients, is open to students for clinical instruction, and furnishes good opportunities for practical demonstrations. Board and lodging can be obtained for from $3 to $5 per week.

Baltimore.

SCHOOL OF MEDICINE OF THE UNIVERSITY OF MARYLAND.—This institution was organized in 1807 as the College of Medicine of Maryland, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 11 professors, 44 associates and lecturers, etc., a total of 55. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Besides this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 10,820 patients were treated in 1901; the Hospital for the Relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital, and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges. The laboratories and lecture-rooms are ample and well equipped. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instruction, special attention being paid to bedside work, make up the system of teaching. The course covers four years of seven and a half months each, and is graded. The total fees for the first two years are $120 each; for the third year, $110, and $140 for the final year. The Dean is Dr. R. Dorsey Coale, Baltimore. The total number of students registered in 1902-3 was 392; graduates, 96. The ninety-seventh session begins Oct. 1, 1903, and will terminate May 15, 1904.

COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty numbers 49. The clinical facilities, besides those afforded in common with other schools, are supplied by the Baltimore City Hospital; the Hospital for the Colored Race, containing 100 beds; the Nursery and Child's Hospital, with 150 beds; the Maryland Lying-in Asylum, and a college dispensary. This school is a member of the Association of American Medical Colleges. The work covers a graded course of four years, seven months constituting a year. Total fees are $115, $110, $110 and $130 for the respective years. The Dean is Dr. Thomas Opie. The total number of students registered in 1902-3 was 315; graduates, 76. The next session opens Oct. 1, 1903, and closes May 1, 1904.

BALTIMORE MEDICAL COLLEGE.—This college was organized in 1881, and has a faculty of 31. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital, the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, besides the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. This college belongs to the Association of American Medical Colleges. The college buildings afford ample laboratory, clinical and lecture-room space. Bedside teaching in the hospital wards is carried on in sections and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of seven months each. The Dean is Dr. David Streett. The total number of students registered in 1902-3 was 410; graduates, 93. The twenty-third session opens September, 1903, and closes April, 1904.

WOMAN'S MEDICAL COLLEGE.—This school was organized in 1882 and has a faculty of 18 professors, 9 associates, assistants and lecturers, a total of 27. The Hospital of the Woman's Medical College and a college dispensary furnish general clinical material, while abundant special material is furnished by the Presbyterian, Eye and Ear and the Sheppard and Enoch Pratt Hospital (for mental cases). The college is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are equipped with all necessary apparatus; the practical work is emphasized. Eight months constitute a school year, and the course covers graded work for four years. The total fees for the first three years are $106 each, and $81 for the last year, with $30 graduation fee. The Dean is Dr. R. H. Thomas, 1718 John St. Total number registered for 1902-3 was 16; graduates, 2. The twenty-second session opens Oct. 1, 1903, and closes May 27, 1904.

BALTIMORE UNIVERSITY SCHOOL OF MEDICINE.—This school, organized in 1884, has a faculty of 10 professors and 25 lecturers, demonstrators, etc., in all 35. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools, supply the facilities for practical work. This college is a member of the Association of American Medical Colleges. The course is four years of six months each. The fees are about $100 each year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St. Total registration for year 1902-3 was 58; graduates, 26. The twentieth session opens October, 1903, and closes April, 1904.

JOHNS HOPKINS MEDICAL SCHOOL.—This is the Medical Department of Johns Hopkins University and was organized in 1893. The faculty comprises 29 professors, 45 lecturers and assistants, a total of 74. The Johns Hopkins Hospital and Dispensary furnishes abundant and varied clinical material; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has, (*a*) completed the chemical-biologic course which leads to the A.B. degree in the university; (*b*) graduated at an approved college or scientific school, and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and such knowledge of physics, chemistry and biology as above indicated. If the candidate is unable to show this, he must pass a satisfactory examination covering the ground. The school is a member of the Association of American Medical Colleges. The laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid on practical work in the laboratories, dispensary and in the wards of the hospital. The first two years are devoted to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years, eight and a half months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented; that fee is $5 a year. The Dean is Dr. William H. Howell, 232 W. Lanvale St. Total registration in 1902-3 was 257; graduates, 49. The eleventh session begins Oct. 6, 1903, and ends June 15, 1904.

MARYLAND MEDICAL COLLEGE.—This school was organized in 1898, and has a faculty of 14 professors, 19 associates, lecturers, etc., 33 in all. The Franklin Square Hospital and a college dispensary furnish clinical material. The course of study covers four years of eight months each. A matriculation fee of $5 and total laboratory fees for the three years of $50 are charged; tuition is $75 each year. The Dean is Dr. J. Wm. Funck, 1631 Eutaw Pl. Total registration for 1902-3 was 204; graduates, 59. The sixth session begins Sept. 15, 1903, and closes in May, 1904.

SOUTHERN HOMEOPATHIC MEDICAL COLLEGE.—This school was organized in 1890, and has a faculty of 11 professors, 21 associates and lecturers, a total of 32. The clinical facilities are those offered by the Maryland Homeopathic Hospital, which has 55 beds, and the dispensary; the obstetric department also furnishes clinical material. Applicants for matriculation must pass a satisfactory examination in English, arithmetic, geography, history, and Latin, unless they possess satisfactory evidence that they have done a corresponding amount of work. The course covers graded work for four years, seven months to the year. The fees are $105 for the first year, $100 each for the second and third, and $130 for the last year; $350 in advance for the full four years' course. The Dean is Dr. George T. Shower, 421 Roland Ave. Total registration for 1902-3 was 26; graduates, 3. The thirtieth session begins Oct. 5, 1903, and ends May 4, 1904.

MASSACHUSETTS.

Massachusetts, population 2,805,346, has four medical colleges: Medical School of Harvard University, Boston University School of Medicine, College of Physicians and Surgeons, and Tuft's College Medical School. They are all situated in Boston, a city of 603,163 inhabitants. Board and lodging can be obtained for from $5 to $7 per week.

Boston.

MEDICAL SCHOOL OF HARVARD UNIVERSITY.—This was organized in 1782, and has a faculty of 26 professors, 112 associates and assistants, etc., a total of 138. Beside the clinical advantages mentioned, the Boston Lying-in Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital, all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case." Each candidate is required to hand in the original note-book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded, and each correlated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; $200 each year. The Dean is Dr. William L. Richardson, 688 Boylston St. The total registration for 1902-3 was 432; graduates, 114. The 122d session begins Oct. 1, 1903, and ends June 24, 1904.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1880, and has a faculty of 24 professors, and 15 lecturers and assistants, a total of 39. Clinical facilities are furnished by the North End Hospital and Dispensary, Union General Hospital, and the city and state institutions. This school is a member of the Association of American Medical Colleges. The course of study covers graded work for four years of eight months each. The total fees for the first year are $100, and for each of the other years about $110, with a graduation fee of $30. The Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered 1902-3, 117; graduates, 19. The twenty-fourth session begins Sept. 25, 1903, and ends June, 1904.

TUFTS COLLEGE MEDICAL SCHOOL.—This school was organized in 1893 as the Medical Department of Tufts College. It has a faculty of 28 professors, 46 assistants and lecturers, etc., a total of 74. Clinical material is furnished by the Boston City Hospital, Massachusetts Charitable Eye and Ear Infirmary, Free Home for Consumptives, Free Hospital for Women, Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also the advantages derived from an out-department in connection with the Boston Dispensary. "Graduates of a high school, college or university, and students having certificates of entrance to a college or university, or holding the State of New York Regents' certificate," also certain approved preparatory school graduates, are admitted without examination; all others must pass an examination in English, Latin, physics and mathematics, including arithmetic, elementary algebra and plane geometry. The laboratories and lecture rooms are ample in their equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course and a final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees are $125 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams, 528 Beacon St. Total number of students for 1902-3 was 349; graduates, 35. The eleventh session begins October, 1903, and ends June, 1904.

BOSTON UNIVERSITY SCHOOL OF MEDICINE.—Homeopathic. This school was organized in 1873; in 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 23 professors, 35 associates and assistants, etc., a total of 58. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 225 beds, a dispensary, a maternity hospital, and the Westborough Insane Hospital; 800 patients. Candidates who have taken their degree in arts, philosophy or science are not examined; all others are examined in English, Latin, French or German or history, mathematics, physics and chemistry. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year are $105; for the second and third, $125 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 295 Commonwealth Ave. Total registration for 1902-3 was 127; graduates, 36. The thirty-first session opens Oct. 8, 1903, and closes June 1, 1904.

MICHIGAN.

Michigan, population 2,420,982, has six medical colleges. Two of these, University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 14,509 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 300,000 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week and upward. Grand Rapids Medical College is located in Grand Rapids, population 87,565. Room and board cost from $3 to $3.50 a week.

Ann Arbor.

UNIVERSITY OF MICHIGAN, DEPARTMENT OF MEDICINE AND SURGERY.—This was organized in 1850, and has a faculty composed of 17 professors, 50 associates, instructors, etc., a total of 67. The University Hospital, with nearly 200 beds, furnishes the clinical facilities. The requirements for admission provide that the applicant, either by certificate or examination, show a sufficient knowledge of the following: English grammar, rhetoric and composition; United States and general history; algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry, these subjects to be accompanied by laboratory work; German or French and Latin. The laboratories and their equipment are good, and the training in them and in didactic work is thorough. The new medical building accommodating the laboratories of hygiene, bacteriology, physiologic chemistry, pathology, histology, embryology and anatomy is now completed and occupied. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course leading to degrees in both arts and medicine in six years is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan. Total registration for 1902-3 was 455; graduates, 92. Next session begins Sept. 29, 1903, and will end June 23, 1904.

HOMEOPATHIC COLLEGE, UNIVERSITY OF MICHIGAN.—This department of the University was organized in 1875 and has a faculty of 18 professors and 12 assistants, total 20; a part of the teaching force is from the other departments of the University. The Homeopathic Hospital, containing 140 beds, furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. W. B. Hinsdale. Total enrolment for 1902-3 was 76; graduates, 13.

Detroit.

DETROIT COLLEGE OF MEDICINE.—This school was formed in 1885 by the union of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 50 lecturers, instructors, etc., a total of 71. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contain a free disepnsary; Woman's, St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once, $5; tuition, each term, $65; hospital and laboratory tickets, each $10, and diploma fee $30. The Secretary is Dr. H. O. Walker. Total enrolment for 1902-3 was 257; graduates, 62. The next session begins Sept. 23, 1903, and will close May 5, 1904.

MICHIGAN COLLEGE OF MEDICINE AND SURGERY—SAGINAW VALLEY MEDICAL COLLEGE.—These two schools, organized in 1888 and 1896 respectively, have just been consolidated to continue on the site of the former. The faculties numbered 36 and 30 and are combined. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of seven months each. The fees are about $80 to $95 per year; third year $70 and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 W. Adams Ave., Detroit. In the perfecting of the consolidation some of these details may be changed. Total registration for 1902-3 of the Michigan College of Medicine and Surgery was 66; graduates, 19; of the Saginaw Valley Medical College, 83; graduates, 34. The next session begins Sept. 29, 1903, and will end May 1, 1904.

DETROIT HOMEOPATHIC COLLEGE.—This was organized in 1899, and has a faculty of 35. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing certificates of an equal amount of work completed, applicants for admission will be examined in English, arithmetic, history, geography and elementary Latin. The course embraces work for four years of seven months each. Fees: From $70 to $90 per year. The Dean is Dr. D. A. MacLachlan. Total enrolment for 1902-3 was 52; graduates, 14. The next session begins September, 1903, and will close April, 1904.

Grand Rapids.

GRAND RAPIDS MEDICAL COLLEGE.—This was organized in 1897. The faculty is made up of 28 professors and 3 assistants, in all 31. Clinical cases in the U. B. A., St. Mary's, and Woman's Butterworth hospitals, and St. John's Orphan Asylum and a college dispensary are available for study. The course is four years of six months each. The total fees are about $65 for each year. The Dean is Dr. C. H. White. Total enrolment for 1902-3 was 52; graduates, 16. Next session opens Oct. 1, 1903, and closes June 1, 1904.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical colleges: Hamline University College of Medicine, and the two medical departments of the University of Minnesota, viz., the College of Medicine and Surgery and the College of Homeopathic Medicine and Surgery. They are all situated in Minneapolis, a city with a population of 225,000. The various hospitals of Minneapolis furnish ample clinical material, and owing to the proximity to St. Paul, the clinical advantages of that city are Medicine and Surgery. They are all situated in Minneapolis, available. The average cost of board and lodging is $20 a month.

Minneapolis.

COLLEGE OF MEDICINE AND SURGERY.—This department of the University of Minnesota was created in 1883, but at that time its only function was to examine for the degrees of B.M. or M.D. In 1888, by the consolidation and absorption of the Minnesota Hospital Medical College and the St. Paul Medical College, its present status was assumed. The faculty is composed of 31 professors and 53 instructors and assistants, a total of 84. The medical school occupies five buildings, and its laboratories are excellent. The last legislature made an appropriation of $105,000 for an additional laboratory of pathology and bacteriology. Eight large hospitals in the Twin Cities, beside the University dispensary and St. Paul dispensary, afford an abundant supply of material for clinical study. The curriculum covers four years of nine months each, and the work is carefully graded. The entrance requirement of one year of university, in addition to four years of high school work, limits the number of students, but assures a high standard of the student body. Total number of students registered in 1902-3 was 315; graduates, 70. Total fees for each year, $100. The Dean is Dr. Parks Ritchie. The next session opens Sept. 1, 1903, and closes June 2, 1904.

COLLEGE OF HOMEOPATHIC MEDICINE AND SURGERY.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 19 professors and 14 assistants, 33 in all. The primary branches are taught by the professors of the College of Medicine and Surgery. The course is graded, extending over four years of nine months each. The total fees for the first two years are $100 each, and $80 each for the last two years. The Dean is Dr. Eugene L. Mann. Total number of students registered in 1902-3 was 18; graduates, 6. The next session opens Sept. 1, 1903, and closes June 2, 1904.

HAMLINE UNIVERSITY COLLEGE OF MEDICINE.—This was organized in 1883. Its faculty is composed of 23 professors, 17 instructors and assistants, a total of 40. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary equipment. Clinical work is offered to the student in City Hospital, Asbury Methodist Hospital, Swedish, St. Barnabas' and St. Mary's hospitals in Minneapolis, Bethesda Hospital, City and County, and St. Joseph's, in St. Paul, and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years, nine months making a year. Total fees, first year, $85; second year, $87.50, and for each of the last two, $80. The Dean is Dr. George C. Barton. Total number of students 1902-3 was 123; graduates, 34. The next session begins Sept. 15, 1903, and ends June 8, 1904.

MISSOURI.

Missouri, population 3,106,665, has fifteen medical colleges. St. Louis, population 575,238, contains six of these, viz.: St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Marion-Sims-Beaumont College of Medicine, Washington University

Medical Department, and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 163,752 inhabitants, has six colleges, namely: Kansas City Medical College, University Medical College, the Hahnemann Medical College of Kansas City, Woman's Medical College, Medico-Chirurgical College and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth Medical College and Central Medical College are located in St. Joseph, population 105,000; board and room can be had for from $3.50 to $5 a week. Department of Medicine of the University of Missouri is at Columbia, a town of 5651. Board and lodging can be obtained at Columbia for from $2 to $5 a week.

St. Louis.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1878, and has a faculty of 23 professors, 26 lecturers, instructors, etc., a total of 49. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds; Female Hospital, having 250 beds; City Insane Asylum; City Poorhouse, and the college dispensary. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $70; second, $65; third, $60, and $75 for the fourth year. The Dean is Dr. Waldo Briggs, 2600 Gamble St. Total number of students registered, 1902-3, was 270; graduates, 62. The twenty-fifth session begins Sept. 16, 1903, and ends April 9, 1904.

MARION-SIMS-BEAUMONT MEDICAL COLLEGE.—By the union of Marion-Sims, organized in 1890, and Beaumont Hospital Medical College, organized in 1886, the present school was founded. It is the Medical Department of St. Louis University. The faculty is composed of 40 professors, 55 lecturers and assistants, a total of 95. Clinical facilities are offered by Alexian Brothers' Hospital, with 250 beds; Rebekah Hospital, having a capacity for 50 patients; Josephine Hospital, 50 beds; Mt. St. Rose Throat and Chest Hospital, 150 beds; Good Samaritan Hospital, 50 beds; St. Mary's Infirmary, containing 150 beds; the City Hospital and Insane Asylum, each with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. This school is a member of the Association of American Medical Colleges. The buildings afford ample laboratory and lecture-room space and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $80; for the second and third, $75 each, and $100 for the fourth. The Secretary is Dr. H. W. Loeb, 3559 Olive St. Total number of students registered for 1902-3 was 391; graduates, 88. The next session opens Oct. 1, 1903, and closes May 1, 1904.

WASHINGTON UNIVERSITY MEDICAL DEPARTMENT.—This school was organized in 1891 from the St. Louis Medical College, which was founded in 1842. In 1899 the Missouri Medical College, organized in 1840, was added. The faculty comprises 39 professors, 22 lecturers and instructors, a total of 61. Clinical material is furnished by the St. Louis Mullanphy Hospital, Polyclinic Hospital, Bethesda Hospital and O'Fallon's Dispensary. In addition to these, the City Hospital, Female Hospital, Insane Asylum and Poorhouse are used in common with the other schools. The requirements for admission are higher than those of the Association of American Medical Colleges. The college buildings, of which there are two, furnish the best laboratory and lecture-room facilities. The course is four years of seven and one-half months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year are $121; second, $105, and for the third and fourth years, $100 each. The Dean is Dr. Robert Luedeking. Total registration of students for 1902-3 was 281; graduates, 53. The next session opens Sept. 24, 1903, and closes May 19, 1904.

BARNES MEDICAL COLLEGE.—This school was organized in 1892, and has a faculty of 24 professors and 20 lecturers and assistants, a total of 44. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital, the college dispensary and the outdoor obstetrical department. This college is a member of the Association of American Medical Colleges. The laboratories are well equipped and other facilities ample. The course of study includes graded work for four years of seven months each. The total fees for the first three years are $75 each, and $85 for the fourth year. The Secretary is Dr. Pinckney French, Century Bldg. Total registration for 1902-3 was 495; graduates, 100. The twelfth session opens Sept. 7, 1903, and closes April 21, 1904.

AMERICAN MEDICAL COLLEGE.—Eclectic. This was organized in 1873, and has a faculty of 9 professors and 5 lecturers, etc., a total of 14. Metropolitan Hospital, containing 40 beds; St. Louis City Hospital, and a college dispensary supply ample clinical material. The requirements for admission are those of the National Federation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of seven months each. The total fees are: Tuition $75 per year, dissecting material $5 per year for three years, final examination and graduation fee $25. Total registration for 1902-3 was 78; graduates, 18. The Dean is Dr. M. M. Hamlin, 2900 Lawton Ave. The next session opens Sept. 21, 1903, and closes April 13, 1904.

HOMEOPATHIC MEDICAL COLLEGE OF MISSOURI.—This was organized in 1857, and has a faculty of 26 professors and 5 assistants, total 31. Clinical facilities are offered by the City Hospital, Children's Free Hospital and a college dispensary. The curriculum covers four years of seven months each. Fees: First year, $80; second, $75; third, $60, and $85 for the fourth year. The Dean is Dr. L. C. McElwee. Total registration for 1902-3 was 66; graduates, 13. The next session opens September, 1903, and closes April, 1904.

Kansas City.

KANSAS CITY MEDICAL COLLEGE.—This was established in 1869, and has a faculty of 19 professors, and 26 lecturers, demonstrators, etc., in all 45. The clinical facilities are those of St. Joseph's Hospital, which also contains an out-patient department; the City Hospital, Bethany Hospital, Scarritt Hospital, St. Anthony's Home for Children and the college dispensary. This college is a member of the Association of American Medical Colleges. The building is large and well equipped, the course is graded and the classes in practical work are divided into small sections and required to personally conduct series of obstetric, medical and surgical cases as a condition of graduation. The curriculum embraces four years of seven months each. The total fees for the first three years are $75 each, and $85 for the fourth. The Secretary is Dr. R. M. Schauffler, 302 Deardorff Bldg. Total registration for 1902-3 was 122; graduates, 24. The thirty-fifth session begins Sept. 9, 1903, and ends April 13, 1904.

UNIVERSITY MEDICAL COLLEGE.—This was organized in 1881 as the University of Kansas City Medical Department and in 1888 was reorganized under its present name. Its faculty comprises 21 professors and 25 lecturers and assistants, a total of 46. Clinical material is furnished by the University Hospital, owned by the college, with 200 beds; the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's hospitals, the Children's Home, St. Joseph's Orphan Asylum, and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations and laboratory work and clinics. The school is a member of the Association of American Medical Colleges. The college building, which has been recently enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of seven months each, and the work is graded. The total fees for each of the first two years are $80, for the third $60, and $85 for the fourth year. The Dean is Dr. Samuel C. James, Bryant Bldg. The total number of students registered in 1902-3 was 222; graduates, 63. The twenty-third session begins Sept. 9, 1903, and ends April 27, 1904.

WOMAN'S MEDICAL COLLEGE.—This school was organized in 1895, and has a faculty composed of 44 professors, 6 lecturers and assistants, a total of 50. Material for clinical study and demonstration is furnished by St. Joseph's, Scarritt, German, Sisters', Agnew, St. Margaret's and City hospitals, and the college dispensary. The requirements for admission are those of the Association of American Medical Colleges. The course of study embraces graded work for four years of seven months each. The total fees for the first year are $68; second, $60; third, $55, and $80 for the fourth year. The Dean is Dr. Nannie P. Lewis, 1219 Wyandotte St. Total number of matriculants for 1902-3 was 16; graduates, 1. The ninth session opens Sept. 16, 1903, and closes March 24, 1904.

MEDICO-CHIRURGICAL COLLEGE.—This school was organized in 1897 as the Kansas City College of Medicine and Surgery of Kansas City, Kan., and was reorganized the following year under its present name. Its faculty embraces a total of 61. Clinical facilities are furnished by the hospitals of Kansas City, used in common by the medical colleges, and a college dispensary. The course covers four years of six months each. The fees are: For the first year, $70; second, $65; third, $55, and $75 for the fourth year. The Dean is Dr. George O. Coffin, 400 New Ridge Bldg. Total registration for 1902-3 was 83; graduates, 19. The next session opens September, 1903, and closes March, 1904.

KANSAS CITY HAHNEMANN MEDICAL COLLEGE.—This school was formed by the union of the Kansas City Homeopathic Medical College, organized in 1888, and the Kansas City University College of Homeopathic Medicine and Surgery. It has a faculty of 38. The City Hospital, Homeopathic Hospital, the Sanitarium, Scarritt, University, Women's and Children's, German, Bethany and Children's hospitals are open to its students for clinical study. The college dispensary and clinics also supply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history, and Latin equal to one year's work. The course covers four years of seven months each. The Dean is Dr. S. H. Anderson, 1214 Main St. Total registration for 1902-3 was 71; graduates, 17. The sixteenth session begins September, 1903, and closes April, 1904.

ECLECTIC MEDICAL UNIVERSITY.—This was organized in 1898, and has 22 in its faculty. The curriculum covers four years of six months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. Theodore Doyle. Total students for 1902-3 was 61; graduates, 15. The next session begins Sept. 17, 1903, and ends March 25, 1904.

Columbia.

DEPARTMENT OF MEDICINE OF THE UNIVERSITY OF THE STATE OF MISSOURI.—This department was organized at Columbia in 1872. The faculty includes 12 professors, 20 assistants, lecturers, etc., a total of 32. Clinical facilities are supplied by the Parker Memorial State Hospital and the Boone County Infirmary. A new $40,000 building for the medical laboratories has just been completed and has excellent equipment. Special emphasis is laid on thorough training in the scientific branches which constitute the foundation of medicine. Four years' course, nine months each, carefully graded. The university offers also a combined course of six years, conferring degrees in both arts and medicine. The entrance requirements are a diploma from a good high school, or the full equivalent. There is no charge for tuition, the only expense being a library fee of $5 each year, and small laboratory fees. The Dean is Dr. A. W. McAlester. Total registration of students for 1902-3 was 98; graduates, 12. The next session opens September, 1903, and closes June 1, 1904.

St. Joseph.

ENSWORTH MEDICAL COLLEGE.—This was organized in 1888, and has a faculty of 22 professors and 12 lecturers and assistants, 34 in all. Ensworth Hospital, with 250 beds; City Hospital, containing 40 beds; the State Hospital No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for admission must show by certificate or examination that they possess a sufficient knowledge of English, arithmetic, algebra, physics and Latin equal to one year's instruc-

tion. The building furnishes ample laboratory and lecture-room facilities. The curriculum covers a graded course of four years of seven months each. The fees are about $55 each for the first three years, and $75 for the fourth year. The Dean is Dr. Jacob Geiger. Total enrolment for 1902-3 was 110; graduates, 14. The next session opens Sept. 1, 1903, and closes March 31, 1904.

CENTRAL MEDICAL COLLEGE.—This school was organized in 1894, and has a faculty of 16 professors and 8 lecturers, in all 24. The Methodist and St. Joseph's hospitals, State Hospital No. 2, and the City and County hospitals are available for clinical study; a college dispensary also supplies clinical material. The requirements for admission are the possession of a high school diploma, or its equivalent, or an examination. The curriculum embraces four years of seven months each. Fees: First year, $55; second, $50; third $50, and $75 for the fourth year. The Secretary is Dr. C. A. Tygart. Total enrolment for 1902-3 was 80; graduates, 23. The next session begins Sept. 1, 1903, and will end April 1, 1904.

NEBRASKA.

Nebraska, population 1,066,300, has three medical colleges: The University of Nebraska College of Medicine and John A. Creighton Medical College in Omaha (population 102,555); and Lincoln Medical College, at Lincoln (population 40,169). Board and lodging can be obtained for from $3 to $5 a week.

Omaha.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE.—This was organized in 1880 as the Omaha Medical College. In 1902 an affiliation was entered into with the University of Nebraska, the name being changed to the College of Medicine of the University of Nebraska. As soon as practicable, the first two years will be given only at Lincoln, though at present these courses are given both at Lincoln and at Omaha. The last two years are given only at Omaha. The faculty is composed of 35 professors and 20 lecturers and assistants, total 55. The Douglas County, Immanuel, Wise Memorial, and Omaha Methodist hospitals, together with the college dispensary, furnish an abundance of material for clinical study and demonstration. The course consists of graded studies covering four years of eight months each. The method of instruction consists of didactic and clinical lectures, section clinics, demonstrations, recitations and laboratory work. The college building is well adapted to its purpose, the laboratories being well equipped and the lecture rooms commodious. The fees, including breakage deposits, are $90 for the first two years, and $95 and $90 for the last two years respectively. Total number of students enrolled in 1902-3, 138; graduates, 38. The college is a member of the Association of American Medical Colleges. The Secretary is Dr. Paul H. Ludington, Bee Building. The twenty-third annual session will begin Sept. 22, 1903, and end May 26, 1904.

JOHN A. CREIGHTON MEDICAL COLLEGE.—This school, organized in 1892, is the Medical Department of Creighton University, and has a faculty of 27 professors and 16 associates, lecturers and assistants, a total of 43. The clinical facilities are those of St. Joseph's Hospital, containing 300 beds and having a clinical amphitheater connected with it; St. Bernard's Hospital, with 256 beds; Douglas County Hospital, Presbyterian and Mercy hospitals, and the college dispensary; the material is abundant and varied. The school is a member of the Association of American Medical Colleges. The building, which was completed in 1898, contains excellent facilities for laboratory and lecture-room work, and the equipment is good. In the methods of instruction, including clinical, didactic and laboratory work, special emphasis is laid on practical work. The course of study embraces four years of seven and one-half months each. The total fees for the first two years are $80 each, and $85 for each of the last two years. The Dean is Dr. D. C. Bryant, McCague Bldg. Total number of students registered in 1902-3 was 142; graduates, 29. The eleventh session opens Sept. 22, 1903, and closes May 1, 1904.

Lincoln.

LINCOLN MEDICAL COLLEGE.—Eclectic. This was organized in 1889 and has a faculty of 27. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of thirty-two weeks each. The total fees for the first year are $80; second, $75; third, $75, and $85 for the fourth year, or $255 for all four years together. The Secretary is Dr. M. B. Ketchum. Total number of students for 1902-3 was 86; graduates, 16. The next session begins Sept. 15, 1903, and ends April 20, 1904.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains one medical college, located in Hanover, population 1884.

Hanover.

DARTMOUTH MEDICAL SCHOOL.—This is the Medical Department of Dartmouth College, and was organized in 1797. Its faculty is made up of 17 professors and 6 instructors, 23 in all. The Mary Hitchcock Memorial Hospital, a cottage hospital of 36 beds, supplies the clinical material. Applicants for admission must possess an education at least equivalent to graduation from a registered high school. The laboratories afford good facilities for work. The course covers four years of thirty-two weeks each. Fees: $125 each year. The Dean is Dr. William T. Smith. The total number of students registered for 1902-3 was 65; graduates, 14. The work for the first and second years begins with that of the academic department, commencing Sept. 24, 1903, and closing April and June, 1904, respectively; for the advanced classes it begins July 14, 1903, and ends in February, 1904.

NEW YORK.

New York State, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Eclectic Medical College of the City of New York, Cornell University Medical College and the University and Bellevue Hospital Medical College, are located in New York City, population 3,437,202. This city, with its hospitals and dispensaries, offers abundant clinical material. Board and lodging can be obtained for from $5 to $7 a week.

Albany Medical College is in Albany, a city of 100,000 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population 352,387; here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city with 108,374 inhabitants. Board and lodging can be procured for from $3.50 a week upward.

The laws of the state of New York require of the prospective student of medicine a preliminary education equivalent to that obtainable in a four years' course in any of the public high schools recognized by the regents as maintaining a satisfactory standard. On proof of at least this amount of education, a medical-student certificate will be issued by the state authorities. The colleges, therefore, have a common standard for the requirements of admission.

New York City.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1807 and its present relation, that of Medical Department of Columbia University, was assumed in 1860. The faculty embraces 37 professors and 77 demonstrators, instructors, etc., a total of 114. The Vanderbilt Clinic, where 45,338 patients were treated during the year 1902, and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 116 beds, offer exclusive clinical advantages to students of this school. Beside these, Roosevelt Hospital, containing 238 beds; New York Hospital, with 150 beds; Bellevue, 900 beds; Presbyterian, 350 beds; St. Luke's, 225 beds; General Memorial, 100 beds, and New York Foundling hospitals, together with the Eye and Ear Institute, containing 40 beds; Willard Parker and Reception hospitals, 200 beds; Babies' Hospital, 50 beds; St. Mary's Free Hospital for Children, 120 beds, and the Hospital for Ruptured and Crippled, 250 beds, all offer free clinical teaching to matriculants of this school. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The total fees for the first year are $205; for the second and third, $200, and $225 for the fourth year. Total registration for 1902-3 was 795; graduates, 168. The next session begins Sept. 23, 1903, and ends June 8, 1904.

LONG ISLAND COLLEGE HOSPITAL.—This was organized in 1858 and has a faculty of 9 professors and 64 assistants, instructors, etc., a total of 73. Long Island College Hospital, containing 300 beds and connected with a four-story maternity hospital; Polhemus Memorial Clinic, and Hoagland Laboratory, completely equipped with the most modern apparatus, are all a part of the college. Beside the clinical facilities furnished by these, members of the faculty attend at Kings County, St. John's, Brooklyn, Norwegian, Williamsburg, Methodist Episcopal and the Brooklyn Eye and Ear hospitals, where the students are offered opportunities for clinical study. Many of these also contain out-patient departments, thus permitting advanced students to attend personally to cases. Bedside instruction is also given in the wards. The course covers four years of thirty weeks each. Fees: First year, $195; second, $200; third, $160, and $195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1902-3, was 290; graduates, 40. The forty-sixth session opens Oct. 1, 1903, and closes May 15, 1904. The summer session opens May 11, 1904, and closes Aug. 11, 1904.

CORNELL UNIVERSITY MEDICAL COLLEGE.—This department of Cornell University was established in 1898. The faculty is composed of 39 professors and 103 instructors and assistants, a total of 142. The City Hospital, having 1,000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception, with 200 beds; New York Skin and Cancer; St. Francis having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Infirmary, in addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at New York or at Ithaca and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential feature of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $180 each, and $200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1902-3 was 394; graduates, 60. The next session opens Sept. 30, 1903, and closes June 8, 1904.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 26 professors and 81 instructors, assistants, etc., in all 107. Bellevue and City hospitals,

hospitals of the Workhouse and Almshouse, Manhattan State Hospital for the Insane, Willard Parker and Reception hospitals, Riverside Hospital for Contagious Diseases, Randall's Island, Presbyterian, St. Luke's, St. Vincent's, General Memorial, Gouverneur, Columbus, Harlem, New York Foundling, and the Society for the Lying-in hospitals, the New York Eye and Ear Infirmary, and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a new five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture-room facilities. The course of instruction covers four years of eight months each. Actual clinical teaching, in conjunction with and founded on laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Edward G. Janeway. Total registration for 1902-3 was 311; graduates, 73. The next session opens Sept. 30, 1903, and closes June, 1904.

New York Homeopathic Medical College and Hospital.—This school, organized in 1861, has a faculty of 29 professors and 33 lecturers, instructors, etc., 62 in all. Flower Hospital, adjoining the college and having a completely equipped out-patient department, Metropolitan, Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children furnish the clinical facilities. The course covers four years of seven months each. Total fees for the first year, $110; second, $130; third, $125, and $155 for the fourth year. The Dean is Dr. W. H. King, 64 W. 51st St. Total students registered for 1902-3 was 111; graduates, 29. The next session begins Oct. 6, 1903, and ends May 12, 1904.

New York Medical College and Hospital for Women.—Homeopathic. This school was organized in 1863, and has a faculty of 24 professors, 20 lecturers and assistants, total, 44. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Flower and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of twenty-six weeks each. Fees: First year, $155; second, $135; third, $125, and $155 for the fourth year. The Dean is Dr. M. Belle Brown, 30 W. 51st St. Total registration for 1902-3 was 34; graduates, 8. The next session opens Sept. 29, 1903, and closes May 13, 1904.

Eclectic Medical College of the City of New York.—This was organized in 1865 and has a faculty of 15 professors and 15 lecturers, demonstrators, etc., 30 in all. A college dispensary, Beachonian Dispensary, Manhattan and Red Cross hospitals and Muncie Sanatorium supply clinical facilities. The work covers four years of seven months each. The total fees: First year, $125; second, $125; third, $125, and $155 for the fourth year. The Dean is Dr. George W. Boskowitz. Total registration for 1902-3 was 104; graduates, 13. The next session opens Sept. 23, 1903, and closes May, 1904. This school is a member of the National Confederation of Eclectic Medical Colleges.

Albany.

Albany Medical College.—This school was organized in 1838, and in 1873 it assumed its present relations, as Medical Department of Union University. The faculty is composed of 19 professors and 45 lecturers, instructors and assistants, a total of 64. Albany, St. Peter's, Child's and County hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of seven and one-half months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: Third year, $110, and $130 for each other year. The Dean is Dr. Albert Vander Veer. Total registration for 1902-3 was 165; graduates, 33. The next annual session opens Sept. 22, 1903, and closes May 3, 1904.

Buffalo.

University of Buffalo Medical Department.—This was organized in 1846 and has a faculty made up of 48 professors and 31 assistants, lecturers, etc., a total of 79. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German hospitals and the German Deaconess' Hospital supply amply clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. Bedside instruction is insisted on and the senior students are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The total fees are: First year, $455; second, $55, and $15 each for the third and fourth years. The Dean is Dr. Matthew D. Mann, 37 Allen St. Total registration for 1902-3 was 237; graduates, 45. The fifty-eighth session opens Sept. 28, 1903, and closes May 3, 1904.

Syracuse.

College of Medicine, Syracuse University.—This school was organized in 1872 as the Medical Department of Syracuse University. The faculty is composed of 16 professors and 34 lecturers, instructors, etc., in all 50. Clinical facilities are furnished by St. Joseph's Hospital, with a capacity of 200 patients; Hospital of the House of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum, and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. This school is a member of the Association of American Medical Colleges. The curriculum embraces a four years' graded course, eight months making a school year. The total fees for each of the four years are $130. The Dean is Dr. Henry D. Didama, 424 S. Salina St. Total number of students registered for 1902-3 was 140; graduates, 29. The next session opens Oct. 6, 1903, and closes June 9, 1904.

NORTH CAROLINA.

North Carolina, population 1,893,810, has three medical schools which grant degrees and one which gives only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill (population 1,099) and at Raleigh (population 13,643). The Leonard School of Medicine is at Raleigh. The North Carolina Medical College is located at Davidson (population 904). Wake Forest School of Medicine is at Wake Forest (population 823).

Chapel Hill and Raleigh.

University of North Carolina Medical Department.—This school was organized in 1891, and formerly gave only the work of the first two college years, at Chapel Hill. In 1902 the course was extended to four years by the establishment of a department at Raleigh in which the last two years are given. Degrees will now be conferred, and the faculty in the completed school of medicine numbers 25. It is a member of the Association of American Medical Colleges. The number of students enrolled in 1902-3 was 83; graduates, 4. Total fees are $85 per year. Board, room, light and heat may be had for from $84 to $102 per college year. The President is Dr. F. P. Venable, Chapel Hill. The next session will begin Sept. 7, 1903, and end June, 1904.

Raleigh.

Leonard School of Medicine.—This department of Shaw University was established in 1882 by the American Baptist Home Mission Society to train colored students of medicine. It has a faculty of 11. A free hospital and dispensary supply clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of six months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room costs $2 a week. The Dean is Dr. James McKee. Total enrolment for 1902-3 was 113; graduates, 23. Next session opens Oct. 1, 1903, and closes April 14, 1904.

Davidson.

North Carolina Medical College.—This school was organized in 1893 and has a faculty of 19. A small hospital supplies the clinical facilities. The course covers four years of eight months each. Fees: First three years, $85 each, and $100 for the fourth year. The president is Dr. J. P. Monroe. The total registration for 1902-3 was 67; graduates, 10. The next session begins September, 1903, and closes May, 1904.

Wake Forest.

Wake Forest School of Medicine.—This school was organized in 1902. It only gives the first two years of the medical course. It has a faculty of 5, and last year enrolled 10 students. The fees are $85 a year. The President is Dr. C. E. Taylor, Wake Forest.

OHIO.

Ohio, population 4,157,545, has ten medical colleges. Four of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College, and Pulte Medical College are located in Cincinnati, a city of 325,902 inhabitants. The clinical advantages of Cincinnati are good; beside many smaller hospitals, the Cincinnati Hospital is open to the students for study. Board can be procured in Cincinnati for from $3 to $5 per week. The Laura Memorial Woman's Medical College has ceased to exist.

Cleveland, population 381,768, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 125,560, contains two: Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 131,822 people, has one medical school: Toledo Medical College. It has good clinical advantages. Board and room can be had for from $3 to $5 per week.

The laws of Ohio require that in order to practice medicine in this state, any student not possessing a diploma or certificate showing that he is possessed of the educational advantages required, must pass a satisfactory examination, under the direction of the State Board of Medical Registration and Examination, in the following subjects: Foreign languages—Two years of the Latin language. English—English literature, composition and rhetoric. History—United States history and civics, with reference to the constitutional phases of American history. Mathematics—Algebra through equations and plane geometry. Science—Botany or zoology; physiography or chemistry, and physics. This is the standard adopted by all the medical colleges in the state.

Cincinnati.

Medical College of Ohio.—This is the Medical Department of the University of Cincinnati, organized in 1819, and has a faculty

made up of 24 professors, 26 lecturers and assistants, a total of 50. Good Samaritan Hospital, with 100 beds; Cincinnati Hospital, with 550 beds, and a well-equipped college dispensary furnish clinical facilities. The buildings supply ample laboratory and lecture-room space, and their equipment is good. The course of study is graded and covers four years of eight months each. This school is a member of the Association of American Medical Colleges. The lecture fees are $125 each year for each student entering after July 1, 1903; $100 each year for those who have matriculated prior to July 1, 1903. In addition there is a matriculation fee of $5, payable but once, and a graduation fee of $25. Total registration of students for 1902-3 was 170; graduates, 54. The Dean is Dr. P. S. Conner, Cincinnati. The eighty-fifth session begins Sept. 24, 1903, and ends May, 1904.

MIAMI MEDICAL COLLEGE.—This school was organized in 1852 and has a faculty of 23 professors and 24 lecturers and demonstrators, a total of 47. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. The Presbyterian Hospital, with the Laura Memorial Dispensary, has become a clinical department of the college. The undergraduates of the Laura Memorial College will continue their studies in the Miami College. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of eight months each. The total fees are, for the first year, $130; for the second and third, $125, and $150 for the fourth year. The Dean is Dr. J. C. Oliver, 628 Elm St. The total registration for 1902-3 was 106; graduates, 40. The next session opens Oct. 1, 1903, and closes June 1, 1904.

ECLECTIC MEDICAL INSTITUTE.—This school, organized in 1845, has a faculty of 29 members. The Seton Hospital, Cincinnati Hospital, and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of thirty weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr. F. J. Locke, Newport, Ky. Total enrolment, 1902-3, was 146; graduates, 45. The next session begins Sept. 21, 1903, and closes April 19, 1904.

PULTE MEDICAL COLLEGE.—Homeopathic. This was organized in 1872 and has a teaching force of 18 professors and 14 assistants, 32 in all. Pulte Hospital, Cincinnati Hospital, Bethesda Hospital, Home of the Friendless and Foundlings, and a college dispensary supply clinical material. The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. J. D. Buck. Total enrolment for 1902-3 was 30; graduates, 10. The next session opens Sept. 29, 1903, and closes May 3, 1904.

Cleveland.

WESTERN RESERVE UNIVERSITY MEDICAL COLLEGE.—The Medical Department was organized in 1843. Its teaching faculty includes 21 professors, 30 lecturers, demonstrators and assistants, a total of 51. Clinical facilities are offered students of this school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, having about 150 beds; City Hospital, with 250 beds; St. Alexis Hospital with 250 beds, and the Home of Maternity, with the dispensary service at Lakeside and Charity hospitals. The laboratory chairs are endowed, the teachers devoting their entire time to teaching and research work. The new clinical laboratory has recently been added, where a systematic course of instruction is given. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. Three years of college work are required for admission to first year of medical course. The total fees are $125 for each year. The Dean is Dr. B. L. Millikin, 278 Prospect St. Total enrolment for 1902-3 was 97; graduates, 26. The next session begins Oct. 1, 1903, and closes June 16, 1904.

THE CLEVELAND COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869, and the Medical Department of the Ohio Wesleyan University in 1896, when it assumed its present name. The faculty is composed of 27 professors, 36 lecturers, assistants, instructors, etc., 63 in all. Cleveland General Hospital, Cleveland City Hospital and a college dispensary are used for regular clinical teaching. St. Alexis, St. John's and St. Clair hospitals are utilized for extra-mural clinics. This school is a member of the Association of American Medical Colleges. The school is co-educational. The total annual fees are $120. The curriculum covers four years of eight months each. The Dean is Dr. N. Stone Scott, 604 Citizen's Bldg. Total enrolment for 1902-3 was 86; graduates, 22. The next term opens Sept. 16, 1903.

CLEVELAND HOMEOPATHIC MEDICAL COLLEGE.—This school was founded in 1897 by a consolidation of Cleveland University of Medicine and Cleveland Medical College, the former of which was incorporated in 1850, and is the second oldest homeopathic medical college in the United States. The faculty includes 27 professors and 29 adjuncts, lecturers, etc., 56 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, the Cleveland City Hospital, the Cleveland Maternity Hospital and a college dispensary. The course embraces four years of thirty weeks each. Fees: First year, $110; second and third years, $105 each, and $125 for the fourth year. The Dean is Dr. Gaius J. Jones. Total number of students registered, 1902-3, was 115; graduates, 40. The next session opens Sept. 21, 1903, and closes May 4, 1904.

Columbus.

STARLING MEDICAL COLLEGE.—This school was organized in 1847 and has a faculty composed of 20 professors and 16 lecturers, associates, etc., a total of 36. St. Francis Hospital, which is under the control of this faculty, Hawkes' Hospital of Mt. Carmel, the Lawrence Hospital, and a college dispensary are available for clinical study. This college is a member of the Association of American Medical Colleges. The work covers four years of thirty-two weeks each. Fees: $100 per year; graduation fee, $10. The Dean is Dr. Starling Loving. Enrolment for 1902-3 was 163; graduates, 49. The next session opens Sept. 16, 1903, and closes May 3, 1904.

OHIO MEDICAL UNIVERSITY.—This school was organized in 1890 and has a faculty of 23 professors and 11 assistants, 34 in all. The Protestant Hospital, State Hospital, Ohio Penitentiary Hospital, and a college dispensary provide material for clinical work. This school is a member of the Association of American Medical Colleges. The course is four years of 32 weeks each. Fees: First year, $105; second year, $100; third year, $100, and $110 for the fourth year. The Dean is Dr. George M. Waters. Total students for 1902-3 was 214; graduates, 58. The next sessions begin Sept. 16, 1903, and ends April 28, 1904.

Toledo.

TOLEDO MEDICAL COLLEGE.—The school was organized in 1882 and has a faculty of 17 professors, 21 lecturers and assistants, in all 38. Toledo Hospital, St. Vincent's and Robinwood hospitals, Lucas County Infirmary Hospital, Toledo Hospital for the Insane, and a free dispensary supply clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. The fees are $75 for each year with a matriculation fee of $5, payable once. The Secretary is Dr. Park L. Myers, 1921 Franklin Ave. Total enrolment for 1902-3 was 41; graduates, 14. The next session opens Sept. 24, 1903, and closes May 12, 1904.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, located in Salem, a city of 4,258 people, and University of Oregon Medical Department, in Portland, a city of about 100,000 population. Board and lodging may be obtained in Salem for from $3 to $5 per week and in Portland for from $4 to $6.

Salem.

MEDICAL DEPARTMENT WILLAMETTE UNIVERSITY.—This school was organized in 1864. The faculty consists of 16 teachers. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of six months each. Fees: First year, $110; second, $100; third, $75, and $50 for the fourth year. The Dean is Dr. W. H. Byrd. Total enrolment for 1902-3 was 40; graduates, 7. The next session begins Oct. 1, 1903, and ends April 2, 1904.

Portland.

UNIVERSITY OF OREGON MEDICAL DEPARTMENT.—This department of the State University was organized in 1887 and has a faculty of 14 professors and 13 assistants, lecturers, etc., a total of 27. Good Samaritan and St. Vincent's hospitals, containing 200 and 350 beds, respectively, furnish good material for clinical study. The requirements for admission are those of the Association of American Medical Colleges, but the members of the faculty do not hold examinations for entrance. The college building is modern and well equipped, presenting ample teaching facilities. The course is four years of seven months each. Fees: First year, $142.50; second, $137.50; third, $107.50, and for the fourth, $57.50. The Dean is Dr. Simeon E. Josephi, Portland. Total number of students for 1902-3 was 88; graduates, 10. The next session opens Sept. 16, 1903, and closes April 18, 1904.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has seven medical colleges. Of these Philadelphia, having a population of 1,293,697, contains six, as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, Medico-Chirurgical College of Philadelphia, and Temple College Department of Medicine. The clinical facilities of Philadelphia present abundant and varied material for study. Beside the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. Board and lodging costs from $4 a week upward.

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 321,616 people. The cost of board and lodging is from $4 to $6 a week.

A preliminary examination is required of all applicants for a license to practice medicine or surgery in the state. This examination is held at stated intervals by the state examiners, and includes: (a) English composition, grammar and rhetoric; (b) mathematics, covering algebra and plane geometry; (c) elementary physics; (d) United States history, and (e) Latin equivalent to a year's study. On passing a successful examination a medical student certificate is issued to the applicant. This certificate will admit the possessor to matriculation in any medical college in the state.

Philadelphia.

UNIVERSITY OF PENNSYLVANIA DEPARTMENT OF MEDICINE.—This is the first medical college established in this country, having been organized in 1765 as the Medical Department of the College of Philadelphia; the first degrees were granted in 1768. When from the College of Philadelphia the University of Pennsylvania was organized, in 1791, it became the Medical Department of the University, its present relation. The faculty is made up of 25 professors and 78 assistants, lecturers, etc., a total of 103. Abundant and varied clinical material is furnished by the University Hospital.

capacity 300 beds, which treats over 14,000 cases annually; University Maternity Pavilion, with 50 beds; Philadelphia Hospital, containing 1,000 beds; Pennsylvania, Children's and the Southeastern Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the university. The buildings known as Medical Hall, Laboratory Hall and the Laboratory of Hygiene, the laboratories of pathology, physiology and pharmaco-dynamics, and the Wistar Institute of Anatomy, and the Wm. Pepper Clinical Laboratory supply excellent laboratory and lecture-room facilities and are well equipped. The course embraces study for four years of nine months each. The total fees for each year are $200, with a matriculation fee of $5 for the first year. The Dean is Dr. Charles H. Frazier. Total enrolment for 1902-3 was 469; graduates, 111. The next session opens Sept. 25, 1903, and closes June 15, 1904.

JEFFERSON MEDICAL COLLEGE.—This school was organized in 1825, and has a faculty of 27 professors and 75 lecturers, demonstrators, etc., a total of 102. Jefferson Hospital, together with its Maternity Department, are used exclusively by students of the school for clinical study. Bedside instruction is given daily to small sections of the senior class. In addition, the following hospitals are open for study of clinical cases: Pennsylvania, Philadelphia, St. Joseph's, German, Municipal and Wills Eye hospitals. This college is a member of the Association of American Medical Colleges. The course of study covers graded work of four years of eight months each. The laboratories are large and well equipped, a new five-story laboratory building having recently been added; the lecture rooms and amphitheaters are also ample. A new fire-proof hospital is now building, to cost $700,000, to be finished in 1905. The tuition is $180 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland. The total number of students for 1902-3 was 771; graduates, 166. The next session opens Sept. 24, 1903, and closes May 27, 1904.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.—This school was organized in 1850, and has a faculty of 31 professors and 42 assistants, lecturers, etc., in all 53. Clinical facilities are offered exclusively to this college by the Woman's Hospital and West Philadelphia Hospital for Women. Other clinical advantages offered are those of the Pennsylvania, German, Children's and Philadelphia hospitals, Wills Hospital for Diseases of the Eye and the Philadelphia Lying-in Charity. This school is a member of the Association of American Medical Colleges. The lecture-room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: First year, $140; second, $145; third, $135.50, and $100.50 for the fourth year. The Dean is Dr. Clara Marshall. Total enrolment for 1902-3 was 165; graduates, 30. The fifty-fourth session begins Sept. 23, 1903, and will end May 18, 1904.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.—This school was organized in 1881 and has a faculty made up of 29 professors and 48 assistants, lecturers, etc., 77 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico-Chirurgical Hospital, with 130 beds, and its children's hospital, containing 40 beds, and maternity hospital having 40 beds. In common with other schools the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist and the Philadelphia Lying-in hospitals. This school is a member of the Association of American Medical Colleges. With new laboratories, lecture rooms, a modern hospital and fine clinical amphitheater this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: $150 per annum; matriculation, $5, payable once. The Dean is Dr. Seneca Egbert. Total enrolment for 1902-3 was 431; graduates, 93. The next session opens Sept. 28, 1903, and will close May 28, 1904.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL.—Homeopathic. This was organized in 1848 and has a faculty of 16 professors and 40 lecturers, instructors, etc., in all 56. Hahnemann College Hospital and Pennsylvania Hospital furnish material for clinical work. The requirements for admission are those established by the Intercollegiate Committee of the American Institute of Homeopathy. The work covers four years of thirty-two weeks each. Fees: For each year, $150; matriculation, $5. Total number of students for 1902-3 was 233; graduates, 69. The Dean is Dr. Charles M. Thomas. The next session begins Sept. 21, 1903, and will end May 21, 1904.

TEMPLE COLLEGE DEPARTMENT OF MEDICINE.—This department was organized in 1901, and has a faculty of 37. Instruction is given in the afternoon and evening. The fees are $125 per year. The Dean is Dr. W. Wallace Fritz. The enrolment for 1902-3 was 70; graduates, none. The next session begins Sept. 14, 1903, and ends June 14, 1904.

Pittsburg.

WESTERN PENNSYLVANIA MEDICAL COLLEGE.—This is the Medical Department of the Western University of Pennsylvania, and was organized in 1886. The faculty is composed of 31 professors and 39 associates, assistants, etc., 70 in all. Clinical material for study is furnished by a college dispensary, and the Emma Kaufman Clinic, Relaeman Maternity Hospital, Mercy, South Side, Passavant and St. John's hospitals. This school is a member of the Association of American Medical Colleges. The course of study embraces graded work for four years of eight months each. Special attention is given to practical bedside work. The total fees are $150 for each year. The Dean is Dr. J. C. Lange. Total enrolment for 1902-3 was 317; graduates, 79. The next session begins Oct. 1, 1903, and will close May, 1904.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college, situated in Charleston, a city of 55,807 people. Board and room can be obtained for from $12 to $16 a month.

Charleston.

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.—This was founded in 1823. The faculty is made up of 10 professors and 11 assistants, etc., 21 in all. The clinical facilities are those offered by the City Hospital, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show a diploma of graduation from some literary or scientific institution of learning or a certificate from some legally constituted high school. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. The Dean is Dr. Francis L. Parker. Total enrolment for 1902-3 was 95; graduates, 21. The next session opens Oct. 1, 1903, and closes April 5, 1904.

TENNESSEE.

Tennessee, population 2,020,616, has twelve medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department, Meharry Medical College and Southwestern Presbyterian University Medical Department are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week.

Knoxville, population 32,637, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week.

Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, a city of 30,154 people. Board and lodging cost there from $2 a week upward.

Memphis Hospital Medical College is located in the growing city of Memphis, population 102,320. Good board can be obtained for from $3 to $4 a week.

The University of West Tennessee is in Jackson, whose population is 15,000.

The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 1,200 people.

Nashville.

MEDICAL DEPARTMENT UNIVERSITY OF NASHVILLE.—This school, established in 1850, has a faculty of 13 professors and 14 lecturers, assistants, etc., in all 27. This school is a member of the Southern Medical College Association. The course of study covers four years of twenty-six weeks each. The total fees for each of the four years are $65. The Dean is Dr. William G. Ewing. Total enrolment for 1902-3 was 317; graduates, 50. The next session begins Oct. 1, 1903, and ends March 31, 1904.

VANDERBILT UNIVERSITY MEDICAL DEPARTMENT.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised, and the present faculty of 35, consisting of 18 professors and 17 associates, lecturers, etc., was appointed. The school is a member of the Southern Medical College Association. The course covers four years of six months each. The total fees for the first three years are $105 each, and $130 for the fourth year. The Dean is Dr. William L. Dudley. Total enrolment for 1902-3 was 162; graduates, 34. The next session begins Oct. 1, 1903, and ends April 5, 1904.

UNIVERSITY OF TENNESSEE MEDICAL DEPARTMENT.—This was organized in 1876 as the Nashville Medical College; its present relations were assumed in 1879. The faculty is composed of 14 professors and 13 lecturers, assistants, etc., 27 in all. The school is a member of the Southern Medical College Association. The course of study includes work for four years of six months each. The total fees for each of the first three years are $90, and $65 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St. Total enrolment for 1902-3 was 150; graduates, 33. The next session begins Oct. 1, 1903, and ends April, 1904.

MEHARRY MEDICAL COLLEGE.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity of obtaining a medical education." The faculty is made up of 10 professors and 12 instructors, demonstrators, etc., 22 in all. The work embraces a four-year graded course, six months to the year. The total fees for the first three years are $40 each, and $50 for the fourth year. The Dean is Dr. G. W. Hubbard. Total registration for 1902-3 was 252; graduates, 41. The twenty-eighth session begins Sept. 2, 1903, and ends in March, 1904.

SOUTHWESTERN PRESBYTERIAN UNIVERSITY MEDICAL DEPARTMENT.—This department, just established, will begin its course this fall. Dr. J. W. Brandau is Dean. About 16 members of the faculty have been selected.

Knoxville.

TENNESSEE MEDICAL COLLEGE.—This school was organized in 1889, and has a faculty of 13 professors and 7 assistants, 20 in all. A new building with large and well-fitted laboratories, has been completed. City General Hospital and a free dispensary supply material for a study of clinical cases. This school is a member of the Southern Medical College Association. The curriculum includes graded work for four years of seven months each. Fees: Matriculation, $5; annual fee, $50; graduation fee, $25. The Secretary is Dr. Henry J. Kelso. Total number of students for 1902-3 was 62; graduates, 8. The fifteenth session begins Nov. 2, 1903, and closes May 23, 1904.

KNOXVILLE MEDICAL COLLEGE.—Colored. This school was established in 1900, following the discontinuance of the Medical Department of Knoxville College, organized in 1895. The teaching force comprises 13. The course covers four years of six

months each. Fees: First year, $42; second, $37; third, $30, and $40 for the fourth year. The Secretary is Dr. H. M. Green. Total number of students for 1902-3 was 23; graduates, 6. The next session opens Dec. 1, 1903, and closes in June, 1904.

Chattanooga.

CHATTANOOGA MEDICAL COLLEGE.—This is the Medical Department of Grant University, and was organized in 1889. The faculty consists of 10 professors and 18 instructors, demonstrators, etc., total 28. Adequate clinical facilities are afforded by the wards of Baroness Erlanger Hospital, a county asylum, an out-door clinic maintained in the college building and all material furnished by the city physician's office which the faculty desire to utilize. The scholastic requirements are those of the Association of Southern Medical Colleges, and involve a strictly graded course covering four years of seven months each. The total fees approximate $65 each session. The trustees have materially added to the general facilities of the institution by the recent erection of another fine four-story building of brick and stone for the medical department, wherein much modern and elaborate equipment has been installed. The Dean is Dr. E. A. Cobleigh. The total enrolment for the session of 1902-3 was 264, of which 41 graduated. The fifteenth annual term opens Oct. 7, 1903, and ends about May 15, 1904.

CHATTANOOGA NATIONAL MEDICAL COLLEGE.—Colored. This was organized in 1898, and claims a teaching force of 18. The course covers four years of seven months each. The total fees are $50 each year with an additional graduation fee of $20. Total enrolment for 1902-3 was 9; graduates, 1. The Dean is Dr. T. W. Haigler, 602 E. 8th St. The next session begins September, 1903, and ends March, 1904.

Memphis.

MEMPHIS HOSPITAL MEDICAL COLLEGE.—This school, organized in 1878, has a faculty of 10 professors and 18 assistants, beside quiz masters. Excellent clinical facilities are furnished by the City Hospital, Presbyterian Hospital, St. Joseph's Hospital and the East End Dispensary, the latter being located in the college building. The course includes graded work for four years of six months each. The total fees for the first three years are $75; for the fourth, $105. The Dean is Dr. W. B. Rogers. Total registration for 1902-3 was 675; graduates, 195. The twenty-fourth annual session will begin Nov. 1, 1903, and close April, 1904.

Jackson.

UNIVERSITY OF WEST TENNESSEE MEDICAL DEPARTMENT.—Colored. This school, organized in 1900, has a faculty of 10. The course is four years of seven months each. The fees are $40 per year, graduation $10 extra. Registration, 1902-3, 17; no graduates. The next session opens Sept. 3, 1903.

Sewanee.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE SOUTH (Sewanee Medical College).—This school was organized in 1891 and has a faculty of 22. It is a member of the Southern Medical College Association. The course is four years of six months each. The fees are $65 for each of the first two years, $55 for the third and $75 for the last year. The Dean is Dr. John S. Cain. Total enrolment for 1902-3 was 203; graduates, 38. The twelfth session commenced May, 1903, and will close January, 1904.

TEXAS.

Texas, population 3,048,710, has six medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month.

The Medical Department of Fort Worth University is at Fort Worth, population 35,000. The cost of board and room in that city is from $12 to $15 a month.

The Baylor University College of Medicine, the Dallas Medical College, the Medical Department of Southwestern University and the Physio-Medical College of Texas are situated in Dallas, population 55,000.

Galveston.

UNIVERSITY OF TEXAS MEDICAL DEPARTMENT.—This department of the State University was organized in 1891 and has a faculty of 25. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infirmary supply good material for clinical study. The requirements for admission are proof, either by certificate or examination, that the candidate is sufficiently proficient in English, including grammar, composition and rhetoric; mathematics through plane geometry and algebra including quadratics, and general history. The curriculum embraces graded work for four years of eight months each. Fees, to residents of the state: First year, $50; second and third each $20, and $5 for the fourth. Non-residents of the state are required to pay an additional fee of $50 each year. The President is Dr. William L. Prather. Total registration for 1902-3 was 179; graduates, 35. The next session begins Oct. 1, 1903, and ends in May, 1904.

Fort Worth.

MEDICAL DEPARTMENT OF FORT WORTH UNIVERSITY.—This school was organized in 1894, and has a faculty of 17 professors and 15 lecturers, assistants, etc., in all 32. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Delia Collins' Rescue Home, having 50 beds, and a college dispensary. The school is a member of the Southern Medical College Association. The course covers four years of six months each. The total fees for each of the first three years are $75, and $100 for the fourth year. The Dean is Dr. Bacon Saunders. The total enrolment for 1902-3 was 108; graduates, 5. The next session opens Oct. 1, 1903, and closes April 7, 1904.

Dallas.

BAYLOR UNIVERSITY COLLEGE OF MEDICINE.—This is a new name for the University of Dallas Medical Department, which was organized in 1901. In June, 1903, it became the Medical Department of Baylor University of Waco. The faculty numbers 19 professors and 21 assistants, total 40. Parkland Hospital, with 90 beds; St. Paul's Sanitarium, Good Samaritan, and Policlinic Infirmary and a college dispensary and hospital are utilized for clinical study. The course covers four years of six months each. The school is a member of the Association of Southern Medical Colleges. The fees are $75 for each of the four years, with a matriculation fee of $5, paid once, and a graduation fee of $25. The Dean is Dr. E. H. Cary. Total registration for 1902-3 was 66; graduates 3. The next session opens Oct. 1, 1903, and closes April 5, 1904.

SOUTHWESTERN UNIVERSITY MEDICAL COLLEGE.—This is the Medical Department of Southwestern University and was organized in June, 1903, with a faculty of 28 professors and 11 instructors, total 39. The first session opens Oct. 1, 1903. The course of instruction is graded and covers four years. Requirements for admission are equivalent to those prescribed by the Association of American Medical Colleges. The fees are: Matriculation, $5, paid once; annual tuition, $75; graduation, $25. The hospitals represented by the faculty and open for clinical teaching are: St. Paul's Sanitarium, City Hospital, Children's Home, Rescue Home, Woman's Home, St. Joseph's Orphanage, St. Matthew's Home for Children, Dr. H. K. Leake's Private Infirmary, Out-door Clinic of the Settlement Home and Presbyterian Home for Children. The Dean is Dr. John O. McReynolds.

DALLAS MEDICAL COLLEGE.—We have been unable to secure information of this school, aside from newspaper reports, the Dean and Secretary having failed to reply to several letters. The school was the Medical Department of Trinity University, but this relation has been severed. Total enrolment, 1902-3, 150 (estimated); graduates, 29. The course is four years of about six months each.

PHYSIO-MEDICAL COLLEGE OF TEXAS.—This college was organized in 1902. It has a faculty of 24 professors and 4 assistants, total 28. The course is four years of twenty-six weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment, 1902-3, 20; graduates, 3. The Secretary is Dr. R. L. Spann. The next session opens Oct. 13, 1903, and closes April 16, 1904.

VERMONT.

Vermont, population 343,641, has one medical school, located at Burlington, a town of about 20,000 people. Board and room costs from $3.50 to $5 a week.

Burlington.

MEDICAL DEPARTMENT UNIVERSITY OF VERMONT.—This school was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 18 professors, and 27 assistants, instructors, etc., in all 45. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four-year high school course or take an examination to show equivalent educational qualifications. The laboratory and lecture-room space and equipment are good. The course of study embraces graded work for four years of seven months each. The total fees for each of the first three years are $115 and $140 for the fourth year. The Secretary is Dr. B. J. Andrews. Total registration of students for 1902-3 was 246; graduates, 31. The fifty-first session begins Nov. 28, 1903, and ends June 25, 1904.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, situated in Charlottesville (population 6,449) and Richmond (population 85,050). The clinical facilities in Richmond are good. Board and room can be obtained for $18 a month, and upward, in Charlottesville, and from $12 to $20 a month in Richmond.

Charlottesville.

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—This school was organized in 1827, and has a faculty of 31. A free dispensary and the new four-story hospital furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1902-3 was 151; graduates, 25. The eightieth session opens Sept. 15, 1903, and closes June 15, 1904.

Richmond.

MEDICAL COLLEGE OF VIRGINIA.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, and in 1854 the present name was assumed. The faculty is made up of 16 professors and 24 lecturers, instructors, etc., a total of 40. Clinical material is furnished by the Memorial Hospital and the City Free Dispensary; an outside obstetric department also furnishes opportunities for clinical work. The magnificient new Memorial Hospital, opened July, 1903, is under the exclusive control of this college for clinical purposes. The State Penitentiary, City Almshouse and other public charities and asylums of the city also afford opportunities for clinical work. This school is a member of the Southern Medical College Association. The buildings are large and contain well-equipped laboratories and amphitheaters. The course embraces four years of seven months each. The fees are $85 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1902-3 was 219; graduates, 35. The next session begins Sept. 29, 1903, and will end May 10, 1904.

UNIVERSITY COLLEGE OF MEDICINE.—This school was organized in 1893, and has a faculty of 19 professors, 34 lecturers, assistants, etc., a total of 53. Good clinical facilities are furnished by

Virginia Hospital, with a maternity department and annex, which was built especially for the purpose of affording bedside instruction; Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, City Jail, State Penitentiary, and a college dispensary. Matriculation is in accord with the rules of the Association of American Medical Colleges, and of the Southern Medical College Association, to both of which this college belongs. The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories. The school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of seven and one-half months each. The total fees are $85 for each year. The Dean is Dr. J. Allison Hodges, Richmond. Total enrolment for 1902-3 was 187; graduates, 44. The next session begins Sept. 29, 1903, and ends May 12, 1904.

WISCONSIN.

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 300,000 people. Clinical facilities are furnished them in common by the County Hospital with 300 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

Milwaukee Medical College.—This school was organized in 1893, and has a faculty of 33 professors and 26 lecturers, instructors, etc., a total of 59. Good clinical material is furnished by Trinity, St. Mary's, and the County hospitals, Milwaukee Hospital for the Insane, and a college dispensary. This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded. The course covers four years of seven months each. The total fees are $120 each for the first three years and $130 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1902-3 was 184; graduates, 43. The tenth session begins Oct. 1, 1903, and will close about May 1, 1904.

Wisconsin College of Physicians and Surgeons.—This college was organized in 1893, and has a faculty composed of 26 professors and 21 associates, assistants, etc., a total of 47. St. Joseph's Hospital, containing 150 beds; the college dispensary, the Milwaukee County Hospital, and the Hospital for the Insane supply facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months each. Fees: Matriculation, paid once, $5; general ticket, $100; for the use of the microscope, a fee of $2 is charged for each course. The Secretary is Dr. W. H. Washburn. Total enrolment for 1902-3 was 102; graduates, 23. The next session begins Sept. 29, 1903, and ends May 26, 1904.

CANADA.

The Dominion of Canada, with a population of 5,335,055 (1900) distributed through seven provinces and the Northwest territories, an area which reaches from the Atlantic to the Pacific, contains only 11 medical colleges. Of these, 4 are situated in Ontario, 4 in the province of Quebec, 2 in Nova Scotia, and one in Manitoba. The distinction between university and college in Canada is definite, namely, the latter is a teaching body only and has no right to grant a degree.

Toronto, Ontario.

University of Toronto, Medical Faculty.—All the lectures and demonstrations are given in the laboratories and lecture rooms of the University; more than two-thirds of the instruction in the third and fourth years are given in the wards and in the pathologic and clinical laboratories. A fifth year is now required by the Ontario Medical Council. The faculty numbers 55. Clinical instruction is given in the Toronto General Hospital, Mercer Eye and Ear Infirmary, Burnside Lying-in Hospital, Hospital for Sick Children, and St. Michael's Hospital. Before commencing students must satisfy, as to qualifications, the College of Physicians and Surgeons of Ontario (Provincial Board). Fees are: Registration (payable once), $5; each of the first four years, $100; fifth year, $50; for the degree of M.B., and M.D., each $20. Number of students registered last session, 427; graduates, 90. The next session will commence Oct. 1, 1903. Trinity Medical College of Toronto, which has been in affiliation, has this year been amalgamated with the University. The matriculants of that school in 1902-3 were 165; graduates, 68.

Ontario Medical College for Women.—This college is not empowered to grant degrees, but it qualifies students fully to take the examination in any university. The faculty numbers 35. The fee for each year is $100, exclusive of hospital and university fees. The number of undergraduates, 1902-3, was 31; graduates, 5. The twentieth session will open Oct. 1, 1903, and continue for eight months.

Kingston, Ontario.

Queen's University.—This school had 205 students registered in its medical department during 1902-3, and graduated 48. The faculty numbers 25.

London, Ontario.

Medical Department of Western University.—This school matriculates students in accordance with the requirements of the Provincial Council and has a course of five years. Victoria Hospital supplies the clinical advantages. The fees are about $90 per year and $25 extra for graduation. This school has nearly a hundred students and from 10 to 20 graduates annually. The next session runs from September to May.

Montreal, Quebec.

University of Bishop's College, Faculty of Medicine.—The course leading to the degree of C.M., M.D., extends over four years of nine months each. The annual fees are $100, which include all practical classes and material for the same. Students must, on entering the study of medicine, pass the college matriculation examination, or, if the license for the Province of Quebec is desired, that of the College of Physicians and Surgeons of that Province. Special facilities are offered for the practical teaching of obstetrics, and undergraduates are obliged to take entire charge of several accouchements before being allowed to take the final examination. Other clinical facilities are offered in the Montreal General Hospital, the Royal Victoria Hospital, the Western Hospital, the Hotel Dieu, and the Woman's Hospital. During the last session the students numbered about 75; graduates, about 10. The next session will open in October.

McGill University, Faculty of Medicine.—This college has a course of four years of nine months each. The faculty numbers 20 professors and 61 assistants, total 81. The total fees for the course are $500. Clinical instruction is given in the Montreal General Hospital, Royal Victoria Hospital, and Montreal Maternity Hospital. Students, except university graduates in arts, must pass the medical matriculation of this university or that of one of the provincial medical boards. Students registered during session 1902-3, 435; graduates in June, 1903, 100. The seventy-second session will commence Sept. 22, 1903.

Ecole de Medecine et de Chirurgie de Montreal.—This is the Montreal branch of Laval University's medical faculty in Quebec. It is a French school, organized in 1845. The faculty numbers 47. The registration, 1902-3, was 229; graduates, 45.

Quebec, P. Q.

Universite Laval, Faculte de Medecine.—This is the Quebec branch of Laval University medical faculty. The course consists of four years. The fees for the entire course are from $200 to $300, according to preliminary qualifications. The matriculants are about 100 annually, and the graduates about 20.

Halifax, Nova Scotia.

Faculty of Medicine of Dalhousie University.—The course consists of four years of eight months each, and leads to the final M.D. and C.M. examination. Prospective students must pass the preliminary examination of the Provincial Medical Board, a university examination or a recognized equivalent. During last session there were 80 students, of whom 20 graduated. The faculty numbers 23, and the next session is from September to April.

Halifax Medical College.—The course is four years of eight months each. Matriculants have to be examined by the Provincial Council, as the college does not conduct entrance examinations. The faculty numbers 30. Fees are about $300 for the whole course and $30 for graduation. The students, 1902-3, numbered 77; graduates, 19. The next session begins Sept. 1, 1903, and ends April 26, 1904.

Winnipeg, Manitoba.

Manitoba Medical College.—This is in affiliation with the University of Manitoba, and has a faculty of 21. Winnipeg General Hospital and St. Boniface Hospital supply clinical material. The fees are $400 for the course of four years. There were 94 students in 1902-3, and 17 graduates.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission to be maintained by colleges belonging to this Association are as follows:

Section 1.—Each college holding membership in this Association shall require of each student, before admission to its course of study, an examination, the minimum of which shall be as follows:

1. In English, a composition on some subject of general interest. This composition must be written by the student at the time of the examination, and should contain at least 200 words. It should be criticised in relation to thought, construction, punctuation, spelling, and handwriting.

2. In Arithmetic, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers, and ratio and proportion.

3. In Algebra, such questions as will bring out the student's knowledge of the fundamental operations, factoring, and simple quadratic equations.

4. In Physics, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics, and acoustics.

5. In Latin, an examination on such elementary work as the student may offer, showing a familiarity usually attained by one year of study; for example, the reading of the first 15 chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary.

Sec. 2.—In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official certificates of reputable literary and scientific colleges, academies, high schools, and normal schools, and also

the medical student's certificate issued by any state examining board covering the work of the foregoing entrance examination.

SEC. 3.—Colleges, members of this Association, may allow students who fail in one or more branches in this entrance examination the privilege of entering the first-year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied.

SEC. 4.—Colleges, members of this Association, are free to honor official credentials issued by medical colleges of equal requirements, except in the branches of study embraced in the last year of their own curriculum.

SEC. 5.—Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least four courses of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year.

SEC. 6.—Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional credit for time on the four years' course as follows: (a) To students having the A.B., B.S., or equivalent degree from reputable literary colleges, one year of time; (b) To graduates and students of colleges, of homeopathic or eclectic medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics; (c) To graduates of reputable colleges of mentistry, pharmacy, and veterinary medicine, one year of time.

SEC. 7.—A college not giving the whole four courses of the medical curriculum, and not graduating students, but otherwise eligible, may be admitted to membership.

At the last meeting of this Association new regulations were adopted. After July 1, 1905, matriculants must have a diploma from a four-year high school or an equivalent education. Full particulars were given in THE JOURNAL, July 25, page 274.

The following colleges are members: Arkansas University Med. Dept., University of Southern California College of Medicine, University of California Med. Dept., University of Colorado Medical School, Denver and Gross College of Medicine, Yale University Med. Dept., Columbian University Med. Dept., Georgetown University Med. Dept., Howard University Med. Dept., National University Med. Dept. of Washington, D. C., American Medical Missionary College, University of Illinois Med. Dept., Illinois Medical College, Northwestern University Medical School, Rush Medical College, Fort Wayne College of Medicine, Central College of Physicians and Surgeons, Medical College of Indiana, Iowa College of Physicians and Surgeons, University of Iowa College of Medicine, Keokuk Medical College, Sioux City College of Medicine, Kansas Medical College, University of Kansas Med. Dept., Hospital College of Medicine, Kentucky School of Medicine, University of Louisville Med. Dept., Kentucky University Med. Dept., Flint Medical College, Baltimore Medical College, Baltimore University School of Medicine, Baltimore College of Physicians and Surgeons, Johns Hopkins University Medical School, University of Maryland School of Medicine, Woman's Medical College of Baltimore, Boston College of Physicians and Surgeons, University of Michigan Department of Medicine and Surgery, Detroit College of Medicine, Michigan College of Medicine and Surgery, Hamline University College of Medicine, University of Minnesota College of Medicine, University of Missouri Med. Dept., Kansas City Medical College, University Medical College of Kansas City, Barnes Medical College, Marion Sims-Beaumont Medical College, St. Louis College of Physicians and Surgeons, John A. Creighton Medical School, Omaha Medical College, University of Nebraska College of Medicine, University of Buffalo Med. Dept., College of Medicine Syracuse University, University of North Carolina Med. Dept., Medical College of Ohio, Miami Medical College, Western Reserve University Medical College, Cleveland College of Physicians and Surgeons, Ohio Medical University, Starling Medical College, Toledo Medical College, University of Oregon Med. Dept., Med. Dept. Willamette University, Jefferson Medical College, Medico-Chirurgical College, Woman's Medical College of Pennsylvania, Western Pennsylvania Medical School, University of Virginia College of Medicine, Milwaukee Medical College, and Wisconsin College of Physicians and Surgeons.

Further information may be had of the secretary, Dr. F. C. Zapffe, 1764 Lexington street, Chicago.

THE SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The following extracts from the Constitution show a portion of the regulations controlling matriculants:

ART. IV. SEC. 3. He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate from some legally constituted high school, general superintendent of state education, or superintendent of some county board of public education, attesting that he has been regularly examined and is possessed of at least the educational attainments required of first grade teachers of public schools or a certificate that he has passed the entrance examination to a university; and a student may be given one month, from the date of his admission, to submit his certificate of qualification.

A candidate for graduation (among other provisions), "must have attended, in a regular and reputable medical college, four full courses of lectures, of not less than six months (26 weeks) each, in four separate years, which is construed to mean that no two courses shall either commence or close in the same calendar year—that is, between January 1 and the ensuing December 31." (Art. VI, Sec. 2.)

The following colleges are members: Medical College of Alabama, Birmingham Medical College, Tulane University Med. Dept., University of Mississippi Med. Dept., University of Tennessee Med. Dept., University of Nashville Med. Dept., University of the South Med. Dept., Vanderbilt University Med. Dept., Tennessee Medical College, Baylor University Med. Dept, Fort Worth University Med. Dept., Medical College of Virginia, University College of Medicine.

The secretary is Dr. G. C. Savage, Nashville, Tenn.

AMERICAN INSTITUTE OF HOMEOPATHY.

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

1. English Composition. Exercise on assigned theme, not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.

2. Mathematics. Arithmetical exercises in (a) vulgar fractions; (b) decimals; (c) percentage; (d) proportion; (e) square and cube root; (f) weights and measures; (g) decimal system. Mensuration. (a) Definition of terms: (b) exercises under the more fundamental rules.

3. Geography (general facts about North America).

4. History. General, with particular reference to human progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language. (a) Grammar; (b) four books of Cæsar, or its equivalent.

The colleges recognized as in good standing by this organization are: Hahnemann Medical College of the Pacific; Denver Homeopathic Medical College; Hahnemann Medical College, Chicago; Chicago Homeopathic Medical College; Hering Medical College; Homeopathic Medical Department of the State University of Iowa; Southwestern Homeopathic College; Kansas City Hahnemann Medical College; Southern Homeopathic Medical College; Boston University School of Medicine; Homeopathic Medical College of University of Michigan; College of Homeopathic Medicine and Surgery of University of Minnesota; Homeopathic Medical College of Missouri; New York Homeopathic Medical College; New York Medical College; Cleveland Homeopathic Medical College; Pulte Medical College; Hahnemann Medical College of Philadelphia.

The secretary is Dr. Chas. Gatchell, 100 State st., Chicago.

THE NATIONAL CONFEDERATION OF ECLECTIC MEDICAL COLLEGES.

The following are the minimum requirements of this confederation, for admission to the freshman year:

2. Good English education, to be attested by (a) first grade teacher's certificate; (b) a diploma from a graded high school or literary or scientific college or university; (c) regent's medical student's certificates; (d) entrance examination.

3. An elementary knowledge of natural history, physics and Latin.

The following colleges are members of this confederation: Eclectic Medical Institute, Cincinnati; American Medical College, St. Louis; Eclectic Medical College, New York; Bennett College of Eclectic Medicine and Surgery; California Medical College; Georgia College of Eclectic Medicine and Surgery; Lincoln Medical College.

The secretary is Dr. John K. Scudder, 1009 Plum st., Cincinnati.

COLLEGE NOTES.

Miscellaneous Items of Interest About Many Colleges.

Oklahoma School Not Yet in Operation.—We announced last year the formation of a new medical college in Oklahoma City. The secretary informs us that the school is not yet in operation.

Medical Department University of Mississippi.—This school is to be opened this fall, but for the present only the first two years' work will be undertaken. The dean is Dr. W. S. Leathers, Oxford.

The Table of Homes of Students.—This table on pages 454 to 457 does not give the statistics of every college, as some colleges failed to furnish, or were unable to indicate, the states from which their students came.

Michigan College of Medicine and Surgery.—This school has established a department of tropical medicine, the lecturers for the coming year being Drs. R. S. Linn and V. J. Hooper, both of whom served as volunteer surgeons in the late war.

Canadian Students in the United States.—In the table indicating homes of students, pages 454 to 457, those marked foreign include Canadians. This will explain the number in the "foreign" column, in certain colleges located near the border.

Southwestern University Medical Department.—The curators and trustees of the Southwestern University of Georgetown, Texas, have accepted the offer made by the Texas College of Physicians and Surgeons of Dallas, to make it the medical department of the University.

States That Have No Medical Schools.—The following states and territories contain no medical colleges: Arizona, Delaware, Florida, Idaho, Indian Territory, Montana, New Jersey, New Mexico, Nevada, North Dakota, Rhode Island, South Dakota, Utah, Washington, West Virginia and Wyoming.

Hospital College Improvements.—The faculty of the Hospital College of Medicine has renewed the contract with Central University of Kentucky for ten years, continuing as the medical department of the university. The university owns the college buildings, which it is said will be altered for the 1904 session.

Teaching Methods.—This is the title of a little publication published by the University College of Medicine, Richmond, Va., a year ago. It has been the subject of a great deal of favorable comment. It indicates the hold modern educational ideas are obtaining in the colleges of medicine. Medical teachers may be glad to read this booklet.

Medical Department Arkansas University.—A committee has been appointed to devise ways and means to erect a new "Folsom Clinic." It is expected to cost not less than $20,000. Dr. H. C. Stinson, superintendent of the State Asylum for the Insane, will hereafter lecture on nervous diseases, in place of Dr. Illing. Dr. J. W. Jenkins has been elected adjunct professor of surgery.

Medical College of Virginia.—This school has a fine new hospital. The patients from the Old Dominion Hospital, formerly used by the college, have been removed to the new Memorial Hospital, and the former building is being converted into laboratories to meet the demand for more room caused by the increase in students. Dr. J. Shelton Horsley, formerly of El Paso, Texas, has accepted the chair of the principles of surgery in this college.

Kentucky University, Continuous Session.—The Medical Department of Kentucky University, beginning October 1, will inaugurate a continuous session, divided into four quarters of thirteen weeks each. The course requires four years, with an attendance of at least two quarters in each year, a student beginning his studies with any quarter. At least forty-two months must elapse between the date of his first matriculation and the date of graduation.

The University of Kansas School of Medicine.—This school is remodeling and refitting the old laboratories and will add several new ones in Snow Hall, from which the natural history collections are being removed for installation in the new Museum Building. By this arrangement they will have some fine rooms for microscopic work. To fill the position of associate professor of anatomy, Dr. G. H. Hoxie, A.M. (Union College), M.D. Zurich, takes the place of Dr. S. W. Williston, who has gone to the University of Chicago.

University College of Medicine.—Arrangements are about perfected whereby the University College of Medicine, Richmond, Va., will obtain the entire ownership of a hospital containing 140 beds. This hospital, which is provided with a large number of private rooms beside the wards, has a spacious surgical amphitheater in addition to the private operating room. It is well equipped with all the accessories of a modern hospital including a free ambulance service. Its x-ray apparatus is called one of the best in the south.

Is the Woman's College Passing?—Among the colleges that have ceased operation in the past two years are the Northwestern University Woman's Medical College, Chicago, and Laura Memorial Woman's Medical College, Cincinnati. The undergraduates of these institutions continued their work in most instances in coeducational schools. There now remain only the Woman's Medical College of Baltimore; the Woman's Medical College of Kansas City, and the Woman's Medical College of Pennsylvania. The question arises: Is the woman's college suffering in competition with the coeducational school?

University of Michigan Department of Medicine and Surgery.—The psychopathic ward now being erected in connection with the hospital of the University of Michigan will be opened early in the fall. This ward will contain forty typical cases of insanity, and these will be used for the double purpose of scientifically studying forms of insanity and for the instruction of students. This department of the University Hospital will be in touch with the insane asylums of the state, and from the latter typical cases of insanity will be sent to the hospital.

New Colleges and Colleges Discontinued.—The following new colleges are mentioned this year: Southwestern Presbyterian University Medical Department, Nashville, Tenn.; University of West Tennessee Medical Department, Jackson; Southwestern University Medical Department, Dallas, Tex. In addition there are two new schools that give only the first two years of the course: Wake Forest (N. C.) School of Medicine and University of Mississippi Medical Department, Oxford. The following colleges have passed out of existence: Dunham Medical College has been consolidated with Hering Medical College, Chicago; Saginaw Valley Medical College has been consolidated with the Michigan College of Medicine and Surgery, Detroit; Laura Memorial Woman's Medical College has ceased to exist, being partially absorbed by the Miami Medical College; the Medical Department of the State University at Louisville, Ky. (colored), has been absorbed by the Louisville National Medical College. In addition, plans are being discussed for the consolidation of the Medical College of Indiana and Central College of Physicians and Surgeons, both of Indianapolis.

The Family Physician to the Medical Attendant at the Health Resort.—A writer in the *Corr.-Blatt f. Schweizer Aerzte* calls attention to an antiquarian catalogue, which lists a number of letters written 1865 to 1888 by prominent Swiss physicians commending certain patients to the care of a physician at a watering place, and posting in regard to the details of each case. Another bunch of similar letters written by a physician at Zurich, still in active practice and addressed to a resort physician, are offered for sale at 37c. each. These facts warrant great care on the part of physicians in the matter of such correspondence, and impose greater prudence on the resort physicians not to allow such letters to be exploited for gain. The article concludes with an appeal to resort physicians to reply to these carefully-written letters, a courtesy and necessity which is too often neglected. The family physician is anxious to know the measures attempted and the results, and will be grateful for any aids in the diagnosis if communicated in writing. Any such communications given orally to the patients are liable to be misunderstood and defectively transmitted.

Societies.

Medical Society of Nova Scotia.—The following officers were elected at the recent annual meeting held at Antigonish, July 1 and 2; President, Dr. M. Chisholm, Halifax; vice-presidents, Drs. Henry E. Kendall, Sydney, and Henry K. Macdonald, Lunenburg, and secretary-treasurer, Dr. W. Huntley Macdonald, Antigonish. Halifax was selected as the next place of meeting.

American Microscopical Society.—At the annual meeting held at Winona Lake, July 29, 30 and 31, the following officers were elected: President, Prof. Thomas J. Burrill, University of Illinois; vice-presidents, Prof. H. A. Weber, Columbus, and F. W. Kuhn, Fort Warner; secretaries, Profs. H. B. Ward, and R. H. Walcott, University of Nebraska, and treasurer, J. C. Smith, New Orleans.

Central Wisconsin Medical Society.—At the annual meeting held in Madison, July 28, the following officers were elected: President, Dr. Edward Evans, La Crosse; vice-presidents, Drs. Thomas W. Nuzum, Brodhead, Ledyard V. Lewis, Sun Prairie, William H. Palmer, Janesville, and Charles R. Pickering, Muscoda; censors, Drs. Walter F. McCabe, Beloit, Theodore W. Evans, Madison, J. C. Cutler, Verona, and W. E. L. Froggart, Cross Plains, and Dr. Charles S. Sheldon, Madison, secretary and treasurer.

Maritime Medical Association.—The thirteenth annual meeting was held at St. John, N. B., July 22 and 23, under the presidency of Dr. Murray MacLaren of St. John. Dr. Galen M. Woodcock, Bangor, was present as a representative of the Maine Medical Association. Drs. Maurice Richardson and E. W. Cushing of Boston were present and contributed papers. The following officers were elected: President, Dr. George M. Campbell, Halifax, N. S.; vice-presidents—for Nova Scotia, Dr. William H. Macdonald, Rose Bay; for New Brunswick, Dr. Alban F. Emery, St. John, and for Prince Edward Island, Dr. Alexander MacNeil, Summerside; treasurer, Dr. John Sutherland, Bedeque, Prince Edward Island, and secretary, Dr. T. D. Walker, St. John, N. B.

NATIONAL CONFEDERATION OF STATE MEDICAL EXAMINING AND LICENSING BOARDS.

Report of the Committee on Curriculum, made at the Annual Session, held in New Orleans, May 4, 1903.

Dr. George W. Webster, chairman of the committee, president of the Illinois State Board of Health, and professor of physical diagnosis and clinical medicine in Northwestern University Medical School, Chicago, read the following report:

Mr. President and Members of the Confederation:

At the meeting of the confederation last year a Committee on Curriculum was appointed, in accordance with the recommendation of Dr. N. R. Coleman in his presidential address. I had the honor to be made chairman of the committee, and it is only fair to the other members of the committee to state that the following report represents only my own personal work and personal views. I make this statement in order that any criticisms may be directed against me and not against the other members of the committee.

In the interests of a higher and improved standard of medical education, and of interstate reciprocity in licensure, and in order that the degree of M.D. may have a definite meaning, at least an approach to a uniform, fixed value, it is desirable that a minimum standard of requirements for graduation in medicine shall be established and maintained.

One of the inalienable constitutional rights of the state is the establishment of standards and the enforcement of regulations in regard to medical education. It seems to be of vital importance that we establish a minimum standard of work in a medical curriculum, to which all states can agree, or to which at least a majority can agree and then have each board of examiners or state board of health adopt this as its standard, just as the National Educational Association did in standardizing the high school course.

The first question is, how shall this standard be obtained or determined; and second, how secure compliance with its requirements? This will never be accomplished by the colleges themselves, nor will it be done by such associations as the American Medical College Association, the Southern Medical College Association, the American Institute of Homeopathy, or similar organizations.

The colleges are many of them influenced, dominated by financial considerations, the spirit of trade, and the college associations by sectarian bias or dogma, and they lack the authority to establish standards and compel recognition of them or conformity to them. This standard can, in my opinion, be established, maintained, compliance with its requirements enforced, only by the concerted action of the various boards of health and examining boards of the Union.

Heretofore the standards established by the American Medical College Association and other similar organizations, have been an outline or definition of a "medical course" in the most indefinite terms: For example, "four years of six months each, in four separate calendar years." Not a word in regard to the number of hours of work in each month or in each year and no specifications in regard to relative amount of time devoted to each study in the curriculum, the order or sequence in which studies should follow each other in the course, nothing in regard to whether the work should consist of lectures only, or of laboratory work, recitations, lectures, and clinics combined, and especially the relative amount of time devoted to each, especially clinics.

The same is true of the requirements of the state examining boards as a general rule. In many states some of the colleges aim no higher than the compulsory standards established by their respective state boards, and if the latter are indefinite and elastic those of the medical school are equally nebulous and hazy. A glance at the curriculums of the various medical colleges shows the same wide variations, no two being alike, either in total number of hours of instruction, total hours in any one year or the time devoted to any one subject in the curriculum. The total hours vary from 5,000 in some to a little over 2,000 in others. The time devoted to clinical instruction varies from over 2,000 hours in some down to a little over 200 in others. The same is true of every subject in the curriculum. Over 500 hours are devoted to the subject of chemistry in some schools, and less than half as many in others. Anatomy varies from over 1,200 as a maximum to 200 as a minimum. One school devotes over 400 hours to the study of physiology, while another has less than 100. Medicine has over 1,200 hours in one and less than 200 in another. In other schools such important subjects as physical diagnosis, pharmacology, etiology and hygiene are not taught at all.

THE CIRCULAR LETTER.

With a view of ascertaining what is actually being done, rather than asking advice as to what should be done, I sent the following circular letter to each medical college in the United States:

Dear Doctor:—At a meeting of the National Confederation of State Medical Examining and Licensing Boards, held at Saratoga, June 9, 1902, I had the honor to be elected chairman of the executive committee of the general committee on curriculum.

I am sending you this communication to ask your assistance and advice in the preparation of my report, which is to be made to the confederation at New Orleans, May 4, 1903.

I am enclosing a list of studies usually embraced in the curriculum of a medical course. Will you, at your earliest possible convenience, fill out this schedule, giving the number of hours devoted to each of the studies named in the medical school of which you are the secretary? If the studies are not put down in the proper year, please change to correspond with the work of your school.

For the sake of advancement in medical teaching, and as one of the elements for a basis of interstate reciprocity, uniformity in the length and character of the medical course seems desirable. That I may have the benefit of the views of the leading educators in medicine on this very important point, I would respectfully request replies to the following questions:

1. Aside from the teaching in materia medica, practice and therapeutics, is a uniform curriculum in all the medical schools of the United States desirable?
2. Is it possible?
3. If desirable and possible, how, in your opinion, is it to be established?
4. Dividing the work under the following heads: Lectures, recitations, laboratory work, clinics, what relative time should be devoted to each?
5. How many hours of actual work in each college year?
6. Over how many months should this be distributed?
7. Over how many years?
8. Do you favor elective work, and if so, in what branches?
9. Any suggestions as to the work or the report of this committee will be gratefully received.

In addition to the answers to the questions, I requested each secretary or dean to fill out the following blank form which I sent him, showing the number of hours devoted to each study in the entire curriculum, and divided the work into lectures, recitations, laboratory work and clinics, extending over a four-year course.

First Year.	Clinics.	Lectures.	Recitations.	Laboratory.
Chemistry.				
Anatomy.				
Histology and Embryology.				
Physiology.				
Pharmacology.				
Physical Diagnosis.				
Surgery.				
Total Hours of Instruction.				
Second Year.				
Chemistry.				
Anatomy.				
Physiology.				
Pharmacology.				
Bacteriology.				
Etiology and Hygiene.				
Pathology.				
Physical Diagnosis.				
Surgery.				
Medicine.				
Total Hours of Instruction.				
Third Year.				
Pathology.				
Obstetrics.				
Dermatology and Syphilology.				
Laryngology and Rhinology.				
Pediatrics.				
Surgery.				
Medicine.				
Total Hours of Instruction.				
Fourth Year.				
Obstetrics.				
Ophthalmology and Otology.				
Gynecology.				
Neurology.				
Mental Diseases and Jurisprudence.				
Surgery.				
Medicine.				
Total Hours of Instruction.				
Total Hours of Instruction in Four Years.				

Name of Medical School.
Signature and Address of Secretary of Dean.

I received the courtesy of a reply from about 20 per cent., and gratefully acknowledge the same at this time. The following statistics have been made up from the reports sent in, as far as it was available. In addition to this, the blank forms have been filled in by myself from information taken from the annual announcements of the colleges. More would have been added had it not been for the fact that the announcements are not definite enough and of such a character as to enable me to determine how much time a particular school devotes to any one study, nor the total number of hours of clinics, lectures, recitations or laboratory work in any one year, or in the entire course.

This doubtless accounts for the failure of so many medical schools to answer my letter or fill out the blank forms.

Every effort has been made to have these statistics as reliable as possible. In compiling these statistics many errors have doubtless crept in, and for any such I offer sincere apologies at this time and will very gratefully acknowledge any corrections which may be sent me. It is my purpose to continue this work and to secure this information from every school in the United States and to present a complete report next year.

Some of the statistics furnished this year had to be discarded because of their very evident unreliability. For example, one school gave as the grand total of hours of instruction in the four years over 25,000. This would make over 30 hours a day, including Sundays and holidays.

From these statistics I have constructed the following tables: First, a table showing the total number of hours of work in each of the four years of the medical course, and the grand total of hours in the entire four-year course. The sum of the latter, divided by the number of schools, gives the average number of hours of instruction in these 43 medical schools. (See Table 4.)

A second table gives the number of hours devoted to each study in each of said schools. The total number of hours devoted to any one branch in all the schools divided by the number of colleges gives us the average number of hours devoted to that particular subject. (See Table 4.)

A third table shows the relative number of hours devoted to clinical instruction.

Finally, a fourth table has been constructed which sums up all the foregoing and condenses it into what might be termed an average curriculum which might be adopted and then required as a minimum standard by the various examining boards.

Against this average curriculum it might be urged that it does not represent the average of work done in all the medical colleges of the United States. This is true, but it does represent the work of those schools from which at least half of the graduates come each year. For example, there were about 5,000 graduates in 1902. The graduates from the colleges in this list made up about 2,500 of that total.

ANSWERS TO QUESTIONS.

Question 1.—Yes, 19; no, 6; doubtful, 1.

Question 2.—Yes, 7; no, 8; doubtful, 10.

Question 3.—"The development of interstate reciprocity will help materially in this direction, as will also the perfected organization of the American Medical Association."—Dr. L. M. Crafts, Hamline University, College of Physicians and Surgeons.

"In my opinion there has to be a different standard in different schools; and it seems to me a Utopian idea to expect that all the medical schools in the country should be based on a uniform curriculum, any more than the various colleges or academies."—C. M. Green, Harvard University.

"Attempts to secure uniformity should only be by frequent conferences of the schools where the matter may be considered on broad and catholic grounds; certainly not by compulsion of the weaker by the stronger, nor by state boards or legislation."—S. Egbert, Medico-Chirurgical College.

"I should be inclined to say that such a condition is impossible of attainment in view of the widely different circumstances surrounding different schools and also because of the widely divergent opinions held by different teachers."—J. C. Oliver, Miami Medical College.

"It should be possible and ought to be regulated by the appointment of a special committee who should determine first the number of years required to cover the course, etc."—G. M. Kober, Georgetown University.

"If established at all it must be by an understanding between state boards of medical examiners and the various medical institutions."—G. H. Price, Vanderbilt University Medical Department.

"The varying conditions that exist in the different medical schools as to the number of students, facilities for laboratory and clinical instruction, and endowment would render such a plan undesirable and impossible."—C. H. Frazier, University of Pennsylvania.

Many no answers at all. A number simply say state board associations.

Question 4.—"It seems to be the tendency of the times to diminish the number of lectures and increase the laboratory work and clinics, recitations being retained as hitherto."—C. M. Green, Harvard University.

Eight no replies. On an average the balance suggest the work given thus: Laboratory, clinics, lectures, recitations, about one-fourth to each.

Question 5.—Average of those giving hours, 1,059.

Question 6.—Average of replies, eight months.

Question 7.—Average of replies, four years.

Question 8.—Yes, 13; no, 10; no replies, 3; most replies "yes" were for specialties.

Question 9.—No suggestions were made.

CONCLUSIONS AS TO QUERIES MADE.

1. At present there is a disgraceful lack of uniformity in the medical curriculum of the medical colleges of the United States.

2. Comparative uniformity in the medical curriculum is desirable in the interests of higher medical education and of interstate reciprocity.

3. It is possible. It can be accomplished by this confederation by adopting a minimum standard and then having this standard adopted by each of the state boards of health or examing and licensing boards.

4. This standard curriculum, which is to be adopted as a minimum requirement for the degree of M.D., should consist of not less than 3,600 hours, divided nearly equally between the four years.

5. The course should consist of four terms in four separate calendar years.

6. There should be at least 900 hours of actual work, or 30 weeks and 30 hours in each week aside from holidays.

7. Clinical work should constitute at least one-fourth of the entire work of the four-year course.

8. The average time devoted to each subject in the curriculum should be approximately that presented in volume two of the advised standard.

9. There should be a minimum standard of required work. If elective work is permitted it should be in addition to the required work.

10. The above is recommended with a full realization of the fact that the value of a college course lies not so much in the facts learned as in the way in which they are learned, the view point obtained, the atmosphere created and that the atmosphere is made, not so much by the dead subjects of its curriculum, but by the living personality of its professors.

It was a realization of this that let a former president of the United States remark that "Mark Hopkins at one end of a log and himself at the other was university enough for him."

In medical education there should be unity of direction, at least comparative uniformity of standards, and the most intelligent methods should prevail.

The ideal curriculum not only compels men to think, but fits them to act, which teaches not only facts, but inculcates correct methods.

GEO. W. WEBSTER, Chairman.
AUG. KORNDOERFER.
J. C. WEBSTER.

EXPLANATIONS OF TABLES 1 AND 2.

c Before the names of colleges means report taken from catalogue.

s Before the names of colleges means report taken from replies by secretaries.

x In the column giving the general average in any one subject means the subject is taught but included in some other subject.

o In the column giving the general average in any one subject means the subject is not taught at all.

SUMMARY OF TABLE 1.

TOTAL NUMBER OF HOURS DEVOTED TO THE MEDICAL COURSE IN THE FOLLOWING SCHOOLS.

NAME OF SCHOOL.	Hours.

Pediatrics	72	60
Ophthalmology and Otology	106	95
Gynecology	145	130
Neurology	82	75
Mental diseases and jurisprudence	27	25

Owing to the limited space and the cost of publication, 67 pages of statistics have been omitted.

BRITISH MEDICAL ASSOCIATION.

The Seventy-first Annual Meeting, held at Swansea, July 28, 1903.

(*By our Special Representative.*)

SWANSEA, WALES, July 31, 1903.

Swansea is a busy and picturesque town of about 94,000 inhabitants. It is the chief seat of the tin-plate trade of England, and is considered to be the most important copper smelting center in the world. This was the second visit of the association to Swansea, the former visit being about the middle of the last century, when the association was still young.

and the medical profession of Great Britain occupied a very different position from what it does now. The progress of the association has been extraordinary, its membership having increased from 1,500 at its first meeting in Swansea to no less than 19,000 at the present time.

Accommodations.

Although only 550 members approximately had registered up to noon of the third day of the meeting, at all of the leading hotels in the town the accommodation for visitors was taxed to the utmost. Owing to the scant accommodations some of the members and guests had to rough it. The small attendance was attributed in some measure to the inaccessibility of Swansea as a place of meeting.

Arrangements.

The arrangements made by the local committee for the reception of the visitors and for their interest and entertainment while in Swansea were admirable. There were receptions, garden parties, excursions, golf and cricket matches galore. There was sufficient variety of entertainment to please the most fastidious.

The meetings of the council, the general and representative meetings were so arranged as not to conflict with the scientific work of the association. The hours assigned for the meetings of all of the sections were from 11 a. m. to 1 p. m. each day.

The Church Service.

The members of the association attended the parish church on Tuesday morning attired in their academic robes. The congregation was very large and included the mayor and town clerk of Swansea and the new president and retiring president of the association. The Rev. Thomas Morris intoned the service, and the vicar, the Rev. Talbot Rice, read the lesson. The Bishop of St. David's preached from the text, "Christ Also Suffered." The bishop pointed to the appropriateness of the attitude of the association in thus seeking divine guidance and inspiration from the Great Physician, who had hallowed for all time the ministry of healing. After referring to the part that suffering played in the affairs of human life, the bishop said that the gratitude of mankind was deeply due to medical science for the discoveries made to reduce human suffering, but pointed to the fact that against the beneficent reduction of pain were to be set the glaring growth of social contrasts and the keener sensitiveness to suffering which attended the progress of modern civilization. It was, however, a healthy sign of the times that statesmanship now recognized more and more the agency of promoting the welfare of the people. In conclusion he reminded his hearers of the constant inspiration to be found in the recollection that Christ, who also suffered, ever associated Himself with suffering humanity.

The President's Address.

The president's address on the evolution of antiseptic surgery and its influence on the progress and advancement of bacteriology and therapeutics was interesting, brilliant and scholarly. He drew a striking picture of the wards and operating theater of a hospital at the time when he and many of his audience were students in the fifties and sixties; when wards were filled indiscriminately with disease and injuries of all kinds; when blood poisoning, erysipelas and suppuration were rife; when absorbent cotton wool was unknown, and the same sets of ward sponges were used for all cases alike. Under such circumstances the mortality of major operations was as high as 33 per cent., whereas now, he said, it is reduced to about 3 per cent., while that from minor operations is practically *nil*. This transformation was due to the evolution of surgery under the influence of Listerism.

The peroration of his entertaining address was unusually good. He said:

> The object of the British Medical Association is to secure concord and fraternity, unity and strength; power to organize and advance knowledge; power to protect our own interests and uphold the honor and noble traditions of the profession; power to promote and keep a jealous watch over the well-being of the community, and to educate them on all matters relating to health, both of mind and body; and, finally, power to influence and guide parliament in legislating for the health of the nation. The possibilities of the association are great; its influence, which is increasing year after year, will last as a living power in the country, and remain a valuable legacy for the benefit of posterity.
>
> Although our profession is not a lucrative one, it is honorable and heaven-born, and we may have the satisfaction of knowing that we are doing noble and Christian work in our effort to cure disease and alleviate human suffering. Moreover, we may claim that we live and labor to procure for the whole civilized world Nature's choicest blessing—health.

The addresses on medicine and surgery were likewise brilliant and scholarly, full abstracts of which will be given in THE JOURNAL.

The Sections.

Owing to the small registration the attendance in the various sections was slim. For instance, in the surgical section, during the reading of an important and interesting paper by Mr. Makins on intestinal anastomosis, there were only 45 present. Contrast this small number with the five or six hundred members in attendance on the Section on Surgery and Anatomy of the American Medical Association at New Orleans, and one will find food for reflection. Again, in the section on laryngology and otology, when no less an authority than Professor Glück of Berlin was demonstrating a case of laryngectomy, after presenting an exhaustive paper on this subject, there were only 25 present. There were only 35 members present in the section on obstetrics and gynecology when an interesting discussion was going on relative to fibroid tumors complicating pregnancy.

Discussions Not Reported Stenographically.

The discussions on papers read before the sections are not reported by shorthand writers, as is the custom at the annual sessions of the American Medical Association, but each discusser is furnished with a writing pad immediately at the close of his remarks by one of the secretaries. On each pad is printed the following: "Please write out your speech before leaving and hand it to the honorary secretary of the section. Please write name and number on each slip distinctly." As it takes considerable time to write out the remarks of a five or ten-minute speech, the secretaries are kept busy supplying the different speakers with writing pads and collecting them. Sometimes from four to six pads are in use at the same time. This method does not seem to curtail discussion in the least. The speakers willingly and cheerfully, apparently, write out what they have said; but there was a vast difference between the written speech and the spoken one, as we had occasion to observe by comparison. Interesting points that were brought out in the spoken speech were omitted from the written one. It is said that the British Medical Association has never tried to have its scientific discussions reported stenographically at these meetings on account of the great scarcity of competent medical stenographers in England, hence its adherence to the present method.

Excitement in the General Meeting.

The general meetings of the association, like those of the American Medical Association in former years under the old plan, are not as serene as they might be. Dr. E. W. Skerritt, Bristol, treasurer of the association, having submitted the financial statement, Dr. B. Bell, Glasgow, offered some piquant criticism thereon. He wanted more information as to how the money was spent. As it was, the members were asked to pass the accounts without knowing where the money went, and he said something should be done to remedy this unbusinesslike state of affairs. The *British Medical Journal* was conducting a large business, and the business ought to be conducted by business men and not merely by members of the council. He believed a great deal of money was spent that might be saved, and considered that the manner in which the journal was conducted was simple disgraceful. Apropos of the latter remark there were emphatic protestations and cries of "No, no." The speaker proceeded to move a set of resolutions aiming at reform, but was squelched with interruptions.

A representative defended the commercial ability of the members of the council. The accounts, he said, were published in detail in the journal, and if the members read the journal some of them would not have such extraordinary notions. Another member said he was instructed by his division not to

criticise the profit and loss account, but to ask for more details in the future.

The president regarded the questions raised by the members as childish, to which remark there was a chorus of very emphatic noes. The treasurer having replied to some of the points raised in a very satisfactory manner, the financial statement was adopted.

Absence of a Conspicuous Figure.

Last year, owing to ill health, Mr. Francis Fowke, after thirty-one years' faithful service as general secretary, tendered his resignation. This was accepted with general regret, and the association elected him an honorary member. During Mr. Fowke's term of office he guided the affairs of the association with conspicuous ability. When appointed he found the finances in a far from satisfactory condition, but by his close attention to every department he was able to change this condition of uncertainty to one of great stability. He watched the numbers of the association increase from about 5,000 tc close on to 19,000, and helped to start branches in India. Australia, Canada, Africa and other parts of the British Empire beyond the seas.

The council has appointed Mr. Guy Elliston general secretary, who has been associated with Mr. Fowke for upward of three years. It is believed that he will prove a worthy successor in this important office.

Organizer Appointed.

The association, in recognizing the great importance of thoroughly organizing the medical profession throughout the British Empire, has appointed Mr. J. Smith Whitaker organizing secretary, to take charge of the business of the medico-political organizing and ethical committees.

(*To be continued.*)

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Thirteenth Annual Meeting, held at New Orleans, May 4, 1903.

(*Concluded from p. 386.*)

For National Uniformity of Curricula.

Dr. Geo. M. Kober, Washington, moved that the special committee on by-laws, consisting of Drs. Ritchie, Dodson and Wathen, be continued, and that this committee be instructed to present some method at the next meeting for unifying the teaching in medical colleges.

Carried.

Appreciation of the President's Address.

Dr. J. W. Holland reported for the committee on president's address, as follows:

"We desire to express a very high appreciation of the valuable suggestions made by the president, and to recommend that a vote of thanks be extended to him by the Association. Further, that the address be printed, and that the suggestions contained therein, and which have not already been adopted, be referred to the committee on by-laws with a view to considering and presenting these matters at the proper time."

[Signed.] H. O. Walker.
J. W. Holland,
H. B. Ward.

On motion the report was accepted, and a vote of thanks extended to Dr. Rodman.

The Officers Elected.

The nominating committee then reported as follows: President, J. R. Guthrie, Dubuque, Ia.; first vice-president, Geo. M. Kober, Washington, D.C.; second vice-president, J. C. Oliver, Cincinnati; secretary-treasurer, Fred. C. Zapffe, 1764 Lexington street, Chicago; judicial council, John M. Dodson, Chicago; Randolph Winslow, Baltimore, H. B. Ward, Lincoln, Neb., J. W. Holland, Philadelphia. On motion the report was adopted, and the secretary instructed to cast the ballot, which he did.

Dr. P. Richard Taylor moved that the amendments as adopted be printed and mailed to the members of the Association within thirty days. Carried.

The suggestion in the secretary's report with reference to appointing a committee of three to assist the secretary in furthering the enrollment in the Association of colleges not now members of the Association, was referred to the committee on by-laws.

The Association then adjourned.

Wm. L. Rodman, President.
Winfield S. Hall, Secretary.

The following arguments were submitted, but on account of lack of time were read by title.

Symposium: To What Extent and How Rapidly Shall Our Standards of Admission to Medical Schools Be Advanced?

BY PARKS RITCHIE, DEAN COLLEGE OF MEDICINE AND SURGERY, UNIVERSITY OF MINNESOTA, MINNEAPOLIS.

The ostensible purpose in the organization of this Association was the advancement of medical education. We have met year after year and resolving ourselves into a mutual admiration society have enjoyed a pleasant social reunion. We have heard many admirable papers on the theory of higher medical education, and have indulged in delightful utopian dreams of the possibilities of the future ideal medical school. We have formulated rules for our guidance, and when a school has been convicted of flagrant violation, a *mild* reproof has been *firmly* administered!

Three years ago we made an apparent step forward, but by the wholly unauthorized and grossly unjustifiable action of the former secretary, and the chairman of the judicial council, the will of the Association was nullified.

The time has come for "the parting of the ways." Either we have fulfilled our mission and should disband, or we should take some action to justify our existence. Everyone must concede there is no crying demand for more practitioners. On the contrary, in the near future it must become a struggle for a bare livelihood.

The cheapness and ease with which a medical diploma may be secured is an invitation to ignorant and incompetent men to enter an already overcrowded profession. The number of cheap medical schools is appalling, and the unseemly strife for students in some localities is most disgraceful. What remedy offers for this unhappy situation? Consolidation of schools, which have demonstrated their fitness to survive, and the abandonment of the inferior grade, which have neither endowment, equipment nor ability.

This last proposition is humanly improbable of voluntary accomplishment. How shall the weak and consequently unworthy medical school be forced into bankruptcy and extinction? By the united efforts of the better grade of schools of this Association in an attempt to dignify the profession by limiting its membership to men with some degree of education, demonstrating that ours is not a mere trade to be taken up by any illiterate fellow who has the necessary funds.

Our entrance qualifications are absurdly low and wholly inadequate; and when we remember that these slight barriers are continually disregarded by members of this Association, the situation becomes intolerable. Any one of you who conducts correspondence with student applicants, knows this to be an indisputable fact.

In five or more states, the examining boards have increased the entrance demands to a degree which excludes the graduates of schools which admit students on our minimum requirements. This Association, which should be the pioneer and leader in this movement, is but a craven follower because it needs must!

If we raise our minimum demand to a high school entrance, the number of students will be greatly reduced. Is that a misfortune? Certainly not from a professional standpoint. Our revenue will be curtailed, but our power for good and our self respect will be exalted. If we move up as one man our united effort will compel endorsement. If we drift along in the futile fashion of the past few years, we lose our opportunity. If we obstruct the wheels of progress because some weak members may lose their doubtful patronage, we degrade ourselves and our vocation to the level of the tradesman.

If some good fellow and his "alleged" college are submerged in the rising tide, he may be considered an "offering" on the altar of higher education and enlightened progress, and ought to be proud of the opportunity to play the star part once. "Let us be up and doing." Now is the time and this the place to assume our station at the right of the column. Let us sternly enforce our rules, and expel unworthy schools which use this organization to advertise scientific wares which exist only in their prospectus. It will purify the air, advance our cause, and make a membership in this Association a badge of high endeavor.

BY SENECA EGBERT, DEAN OF THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

In order that there may be no misunderstanding of the attitude of my colleagues and myself in regard to the question under discussion, I would very positively state that I believe that there should be some reasonable and, perhaps, considerable increase in our requirements for entrance into colleges belonging to this Association, not only because the rules and enactments of certain State Examining Boards and State Boards of Health practically compel us to make the change if we are to maintain the dignity and prestige of our Association in their opinion; but also and more especially because the exigencies of the time demand a higher standard.

But there are certain facts and conditions of which we must not lose sight, but all of which we must carefully consider if we are to solve our problem correctly and at the same time maintain the unity and harmony of the Association.

First, in undertaking to raise our standard, we must distinguish between that which is necessary as a preliminary education and that which is unnecessary but desirable, the latter including the knowledge, education and training of a Huxley, a Spencer or a Darwin.

Second, our change must not be too sudden nor too severe, else it will work injustice to many and thus may do more harm than good. No one can deny that conditions to-day are immeasurably superior to those existing at the time of organizing this Association, and we are in favor of a standard of preliminary education much higher than could have been required generally at that time. Let us then have faith that the coming years will justify and demand still greater advances from us, and the ultimate attainment of the ideal of any one here present.

Again, we must not forget that our standard must be elastic enough to apply to all parts of our country; at least, to all the territory covered by the respective schools of our membership; and sufficiently catholic to satisfy practically the essential requirements of any state board, two features that I believe are entirely compatible and easy of attainment. But to secure this we must have the manifestation of the spirit and not the fixation-and-vexation-of the letter in our law. In other words, we should ask of our entering students quality, not quantity, substance rather than time of preparation. We should not insist on diplomas when certificates from reputable and recognized instructors, or a fair and thorough examination by a duly authorized, competent and impartial educator can and does assure us that the candidate is reasonably well-prepared to take up and go on with the study of medicine. And we must remember that, from a pedagogical standpoint alone, the educator (using the word in a broad sense) of our students does not stop short when they enter our colleges, but that our own courses, as at present required by the demands and needs of the profession, are developmental in a high degree.

It is also worth recalling that the best preparatory schools of to-day are usurping part of the one-time work of the literary college, and that they may and do include in their set courses leading to the acquirement of their diplomas much that may come under the head of what is unnecessary in the preliminary education of a medical student.

Lastly, and with emphasis, I believe that it is far more important that this Association should be scrupulously fair to all its members than that it should raise its standard to the detriment of any considerable number of them, however much the latter may seem necessary. Colleges in affiliation with the so-called state universities have an advantage, that can not be gainsaid, over those institutions which are more or less dependent upon their own energies and private enterprise, and the representatives of the former should be broad-minded and generous enough not to use this advantage unduly or other than fairly to all concerned. This is the Association of American Medical Colleges—not of the colleges connected with state institutions—and our purpose of association is to advance the standard of medical education throughout the whole country. Can we afford then to do anything which causes the least suspicion that the organization has been used to further the interests of even one of its members against the others?

I am ready and willing to amend Article III of our constitution, but with all due respect to the committee, I think we can amend their amendment for the better.

BY C. E. M'CLUNG, DEAN, SCHOOL OF MEDICINE, UNIVERSITY OF KANSAS, LAWRENCE.

In a discussion of the entrance requirements to the medical schools of the country, due regard must be had to the difference between what is reasonably necessary and what is academically desirable. Local conditions must be met and plans laid to secure the best possible results under the greatest variety of conditions. What is really desired from the secondary schools are well trained students. More and more is it becoming evident that the best training is not always secured by forcing all students to pursue exactly the same course of study.

Medical schools would doubtless consider it desirable if students could come prepared in the modern languages, higher mathematics, and the elementary physical and biological sciences; but, is such a training necessary; or is it even possible in most of the secondary schools? I think few will insist that it is either.

What then is the minimum necessary for thorough work in the medical school? I should be inclined to say that a good four-year high school course is the least that will meet the requirements of the present medical curriculum. In such a course I feel sure that all would agree in making an absolute requirement in English and mathematics. Students well trained in these branches almost invariably prove good students.

Aside from these subjects, it would not seem wise to make a rigid requirement of the high schools. The committee proposing the amendment to the constitution has been wise in making provision to meet local sentiment and conditions by allowing the entrance requirements to the freshman class of the state university to serve as a fulfillment of the requirements of the medical school. These institutions register the possibilities of the high schools of their states. As a rule they demand all that it is possible to secure of the secondary schools. They are also finding it wise and prudent to take from the schools the work they are best prepared to give.

Reasonable objection can scarcely be made to the entrance requirements called for by the proposed amendment. It is certainly in the interests of both the public and the profession. A young man of average ability can finish the work of a four years' high school course at the age of eighteen, and be ready for the practice of his profession by the time he is twenty-two or three. He is then young enough to adapt himself to the conditions under which he will pursue his life work, and, at the same time, he has prepared himself measurably well in the subjects that will make him strong as a man. Surely the physician should be a man of high character and ideals, and a leader in his community. Such he probably will not be if he finishes his general education at the eighth grade, and then narrows down to the grind of his purely professional studies.

And why should not the medical schools demand adequate preliminary training of their students? There are plenty of high schools in the country to educate young men to the standard contemplated by the proposed amendment, so that there would be no lack of students, even were this selfish point

of view to be taken. No one can doubt that it would be to the advantage of the medical schools to have better trained students. If it be true then, as I think it is, that benefit would accrue to public, physician, and school by insisting on better preparation for medical work, certainly only a doubtful expediency would suggest contentment with anything less desirable.

BY HENRY S. TAYLOR, ALBANY, N. Y., REPRESENTING THE REGENTS OF THE UNIVERSITY OF NEW YORK (BY INVITATION.)

The topics of discussion before the Association of American Medical Colleges for this session are of keen interest to me. A feeling prevails that the increase of physicians in the United States is out of proportion to the increase in population. The accompanying table shows that in 1860 there was one physician to 576 people; in 1870 one to 617; in 1880 one to 585; in 1890 one to 598; and in 1900 one to 575. In 40 years the population increased nearly two and a half times, but the ratio of population to physicians is practically the same to-day as it was 40 years ago. But, as the number of physicians to the number of persons increased during the last decade more markedly than in any preceding decade, it is fair to assume that the requirements for admission to the practice of medicine should be increased if the general ratio of the 40 years is a proper one.

Table showing ratio of physicians to population as shown by the United States Census:

U. S.	1860.	1870.	1880.	1890.	1900.
Physicians	54,543	62,448	85,671	104,805	132,002
Population	31,443,321	38,558,371	50,155,783	62,622,250	75,994,575
Ratio ...	1 to 576	1 to 617	1 to 585	1 to 598	1 to 575

Assuming that it is safe to advance the requirements for admission to the practice of medicine throughout the United States, should this advancement be made in the general preliminary educational requirement for admission to the medical school, in the professional requirements for graduation, or in both? Without doubt, the new Article 3 strictly enforced will materially advance the preliminary requirements, and a uniform enforcement of the minimum requirements for admission to the medical schools that are members of this Association will materially reduce the numbers of the first class entering on these full requirements. For example, under Item B of Sec. 1, "The diploma of a state normal school having a course of instruction equivalent to a four-year high school course whose credits are accepted by a state university," if interpreted for Massachusetts, will cover a two-year course subsequent to a four-year high school preparation based on eight or nine years of pre-academic or grammar school preparation, which would not be recognized by Harvard for admission to her medical school; while the diploma from an Alabama state normal college secured on a two years' normal course, subsequent to two years of high school preparation, based on six years of pre-academic work, will admit to the junior year of the University of Alabama, i. e., 14 years of scholastic preparation in Massachusetts will not admit to the freshman year of the Massachusetts university, while 10 years in Alabama will admit to the third year of the Alabama university. Hence a uniform enforcement of this section, strictly interpreted, will very materially affect the entrance class to the medical schools of the country. This illustration plainly reveals perhaps the most pressing reform essential to the advancement of the medical profession in the United States to-day, viz., the need of a fixed standard for the measurement of the entrance requirements to professional schools.

The question of advancing the professional requirements is equally important. In the re-registration of medical schools necessitated by New York's advanced statutory requirements, the solution of several important problems leads to the conclusion that an accurate and equitable registration of the medical schools necessitates personal inspection, independent of professional bias. The best available authorities regarding medical schools in 1898 were the American Institute of Homeopathy, the Association of American Medical Colleges, the Illinois State Board of Health, the National Confederation of Eclectic Medical Colleges and the Southern Medical College Association.

A member of the Institute who had served for years on the intercollegiate committee asked regarding the registration of two prominent homeopathic schools by the University of the state of New York. He thought the registration of one of them was a mistake, for that committee regarded it as one of their strongest schools. When he was shown a sworn statement that they made an allowance for admission to advanced standing contrary to the agreement of the committee, he acknowledged that the formal application for registration disclosed conditions not evidenced by annual publications.

The general preliminary educational requirement of the Illinois State Board of Health was plainly below the requirements of the New York statute; hence it became necessary to pass on the general preliminary educational qualification of a candidate for admission to the licensing examination independent of the professional requirement.

The rules of your organization permit an allowance of advanced standing to graduates of schools of dentistry, veterinary medicine, pharmacy, osteopathy, and the like, an allowance not permitted by the New York statute. This has led to the necessity of a distinction between registered and accredited schools, concerning which see the report of the director of the college department for 1902, p. r. 22-30.

The necessity of protecting the interests of students who desire to migrate from weaker to stronger medical schools, made it necessary to register the schools for admission to the licensing examinations independent of the registration for admission to other registered schools. The contention made at your last meeting regarding certain spring schools, that your rules compelled students to remain in such institutions, has some force. A spring school need not necessarily be an inferior school. The relation of receipts to expenditures, of instructors to matriculates, of library, laboratory and clinical facilities to the numbers graduating, are important factors in determining the standing of medical schools which should receive greater consideration than has ever been given them.

Finally, the allowance to be made graduates of colleges of liberal arts and sciences must receive careful attention. The independent colleges and medical schools suffer by the drifting of their students to the universities that can afford both lines of work and a combined course saving one or two years of time. The presidents of independent colleges plead for subjects they regard as essential in liberal culture, while the deans of the independent medical schools plead for these stronger students with the college training. All are agreed, however, that the matriculate possessing the baccalaureate degree, other things being equal, is better fitted for entrance on medical study than the graduate of the high school only. We hope that a satisfactory arrangement of a standardized combined baccalaureate and medical course can soon be adopted by the university that will prove satisfactory to the colleges, universities and medical schools of the State of New York.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Phlegmasia Alba Dolens.

E. C. Hill, in *Med. Standard*, recommends in the treatment of phlebitis complicating the puerperal state, that absolute rest be given the affected limb in a felt-lined splint for 25 or 30 days; linimentum opii et belladonnæ be applied locally, followed by a covering of soft lint or oiled silk, care being observed not to blister. After the second week gentle inunction of mercurial or belladonna ointment should be employed. Later slight compression with bandage should be made. The limb should not be used freely until the fortieth day.

Suprarenal Extract in Diseases of the Skin.

M. F. Engman and W. P. Loth, in *Medicine*, recommends the employment of suprarenal extract in diseases of the skin accompanied by vasomotor disturbances. They regard it of no

benefit in those conditions of the skin attended with inflammation or exudation, such as acne and eczema. They report splendid results obtained in cases of general pruritus such as chronic urticaria, given in five-grain doses three times daily. They invariably use the dried, pulverized extract, gradually increasing the dose unless untoward symptoms are observed, such as nausea, dizziness, tremor, etc. In some cases an accumulative action has been noticed.

Mercury Hypodermically.

Lemoine, according to the *N. Y. and Phil. Med. Jour.*, recommends the following formulæ in the administration of mercury hypodermically:

℞.	Hydrarg. benzoatis	gr. ivss	30
	Sodii chloridi		
	Cocainæ benzoatis, āā	gr. iii	20
	Aquæ destil.	ʒi 30	

M. Sig.: Thirty to sixty drops daily, injected hypodermically; or:

℞.	Hydrarg. bichloridi	gr. ivss	30
	Cocainæ hydrochlor.		
	Sodii chloridi, āā	gr. iss	09
	Aquæ destil.	ʒi 30	

M. Sig.: Seven to fifteen minims daily; or:

℞.	Hydrarg. biniodidi	gr. 3/4	05
	Atropinæ sulph.	gr. 3/40	005
	Aquæ destil.	3v 20	

M. Sig.: Four to seven minims daily; or:

℞.	Hydrarg. peptonatis	gr. iiss	15
	Aquæ destil.	ʒi 30	

M. Sig.: Seven to fifteen drops daily.

Formaldehyd in Acute Tonsillitis.

A. C. Jordan, according to abstract in *Amer. Med.*, has obtained splendid results from the use of formaldehyd in the treatment of acute tonsillitis, aphthous stomatitis, diphtheritic and scarlatinal sore throat. He employs a 1 to 4 per cent. solution in glycerin. This application should be begun early in the disease. It causes some pain, which lasts for several hours, but the pain is not severe. He states that no food or water should be taken for an hour or so after the application in order that the antiseptic effects may not be disturbed. A gargle of potassium chlorate may be used later in the disease.

Dysmenorrhea.

Dr. F. C. Hammond, in an abstract in *Med. News*, states that the cause should be ascertained. However, there is a large class in which the cause can not be definitely worked out. He divides the treatment into:

1. The prevention of the attack.
2. The treatment of the attack.
3. The treatment between the attacks.

In cases in which there is congestion alone, he advises free purgation the day previous to the flow. According to the author the tincture of gelsemium is of great service in cases of dysmenorrhea occurring in girls and where there is a normal anatomic relation. He administers the tincture in ten-drop doses three times a day, beginning a week previous to the flow. He also recommends in such cases the use of apiol, cimicifuga and potassium permanganate.

In the treatment of the attack rest in bed is advised; hot vaginal or rectal douches and a hot-water bag over the abdomen. Antipyrin, cannabis indica, the bromids, caffein, sodium benzoate and viburnum prunifolium are indicated when the pains are of a neuralgic nature. He condemns the use of opium. Nitroglycerin will relieve the condition if the dysmenorrhea is due to vasomotor spasm; it may be given in one-hundredth-grain doses and repeated in an hour if necessary.

In the treatment between the attacks the general health must be cared for by proper exercise, tonics, baths, clothing and elimination.

Local treatment should be employed in order to reduce the congestion by the use of the tampon, antiseptic and astringent applications, vaginal douching, high rectal injections, pelvic massage, etc. In all cases where a pelvic lesion can be made out as the cause of the dysmenorrhea surgical measures should be resorted to in order to effect a cure.

In the neuralgic form of dysmenorrhea apiol may be used, according to *Merck's Archives*, combined as follows:

℞.	Apiol	ʒii 8	
	Acetanilidi	gr. xl 2	65
	Spts. chloroformi	m. xxx 2	
	Alcoholis q. s. ad	ʒii 60	

M. Sig.: One teaspoonful in water every two or three hours.

Antipyrin may be employed likewise, combined as follows:

℞.	Antipyrini		
	Sodii salicylatis, āā	ʒi 4	
	Syr. aurantii q. s. ad	ʒii 60	

M. Sig.: One teaspoonful every hour or two until the pain is relieved.

Shoemaker employs the following combination containing apiolin in the treatment of dysmenorrhea:

℞.	Apiolini	m. l 3	30
	Aloini	gr. i	06
	Sulphuris sublim.	gr. l 3	30

M. Ft. capsulæ No. x. Sig.: One capsule night and morning, one week previous to and during menstruation.

[Apiolin is a camphoraceous substance derived from the root of parsley. Apiol is an oily mixture containing volatile oil, resin and apiolin.]

The following combination is recommended by *Jour. de Med. de Paris* in the treatment of dysmenorrhea:

℞.	Ext. cannabis indicæ		
	Ext. belladonnæ, āā	gr. 1/4	015
	Olei theobromæ q. s.		

M. Ft. suppos. No. i. Sig.: One such to be introduced at night beginning five days previous to the usual time for menstruation.

The following containing camphor and hyoscyamus is frequently prescribed:

℞.	Pulv. camphoræ	gr. xii	75
	Pulv. opii et ipecac.	gr. xx 1	30
	Ext. hyoscyami	gr. xii	75

M. Ft. pilulæ No. xii. Sig.: One pill every two hours until the pain has ceased.

Coryza.

For the relief of coryza, accompanied by obstruction in the nares, Pregnut, in *Lyon Med.*, recommends the following:

℞.	Cocainæ chloralis hydratis		
	Menthol, āā	gr. v	30
	Olei petrolati	ʒii 8	

M. Sig.: Apply locally to the nasal mucous membrane.

Medicolegal.

Presumption as to When Compensation is Due.—The Fourth Appellate Division of the Supreme Court of New York holds, in the case of Bacon vs. Chapman, brought to recover for medical services, that, presumptively, compensation for the services was due immediately on their performance.

Admissibility of Memorandum of Dying Declarations.—The Supreme Court of Wyoming holds, in Foley vs. State, that a paper alleged to contain dying declarations was improperly admitted in evidence, where the statements were written down by one of the physicians in attendance, and the paper was signed and sworn to by him and the other physician and another party, but was not read over to the deceased, and was not signed by him. Under such circumstances, it says, the writing is a mere memorandum. It may be used to refresh the memory of the witness, but is not itself evidence of the declarations of the deceased. To make it admissible, it must have been read over to the deceased, and signed or assented to by him. If, however, the statements contained in the paper above mentioned were admissible as dying declarations, when presented to the jury by competent testimony, the court says that it is not prepared to say that the admission of the paper itself, though erroneous, was prejudicial to the accused or reversible error. The two physicians were present as witnesses, and testi-

fied that the writing contained substantially the dying declarations of the deceased. They were competent to testify to the declarations, refreshing their recollection by reference to the writing, and the error in admitting the paper was thus rather technical and formal than substantial or material. Furthermore, the court says that dying declarations are obnoxious to the objections which, according to the general rule, exclude hearsay testimony. But in view of the fact that in many cases there are no eyewitnesses to the murder except the slayer and the deceased, they are made an exception to the rule, and admitted on the ground of necessity. If they relate to former distinct matters, they do not come within the reason of the exception, and are not admitted.

Power of Court to Order Physical Examination of a Woman.—The personal injury case of Brown vs. the Chicago, Milwaukee & St. Paul Railway Company, the Supreme Court of North Dakota says, presented, for the first time in that jurisdiction, the question as to the court's power to require the party suing in a proper case to submit her person to a physical examination. Here the party suing alleged permanent injury to her uterus and bladder, also the fracture of the hip bone. The trial court took the ground that it was without power to make or enforce an order for the examination of her person by a physician; or that if it was in error on that point, and had such power in a proper case, yet in this case, in view of the party suing being a woman, and in view of the examination necessary under all the circumstances, still would it decline to make the order, for the reason that it would in this case be an ordeal to which she ought not to be subjected. But the Supreme Court holds that the court possessed the power in this case, and that it was an abuse of discretion to refuse to require the party suing to submit herself to the examination of physicians under such reasonable restrictions as the court should prescribe. It holds that in an action to recover damages for personal injuries alleged to be permanent, the trial court has power to require the injured party to submit her person to an examination of physicians or surgeons designated by the party sued, when, in the exercise of a sound judgment, it appears to the court that the necessity of the case demands such an examination. To permit the party suing and a physician of her selection, after examination of her person, to testify that her injury was permanent, and to deny the party sued the privilege of having the alleged injuries examined by competent surgeons to enable them to see from what, if any, injuries she suffered, their nature, extent and probable duration, was an abuse of discretion, and reversible error. The party suing in a personal injury case, by the commencement of her action, impliedly consents to the doing of that measure of justice which she exacts. She can not claim damages for injuries which she conceals from the reasonable inspection of witnesses when such inspection is necessary to equip them to testify on the trial concerning such injuries. She must, so far as in her power, enable the court, jury, and the adverse party to have the best evidence which can be produced in the case. It was no answer to the company's request for an examination that it would offend the modest and womanly instincts of the party suing to require her to submit to an examination of experts. She told a jury of 12 men of her pains; how and when they affected her. She submitted to a digital examination of her injured parts by two physicians of her own selection. It would have been no greater indignity to be examined by other doctors. Neither was it an answer that one physician had examined her and testified to what he found, and was cross-examined by the company. Surgeons of equal learning and honesty may not diagnose an injury in the same way. They may not be equally strong in perception, or equally accurate in observation or in measurements, and thus form different judgments of the existing conditions, which, of necessity, must constitute the basis of their scientific opinions. If a party sued must make his defense against the expert opinions of the chosen surgeons of the party suing, without the opportunity of testing the verity of the basis of such opinions, he may be placed at a disastrous disadvantage, such as the law can not and does not sanction. The company's right was, through an examination, to test the effect and reduce the weight of the evidence introduced by the party suing. The courts of Massachusetts, Texas, and Delaware, in following the Supreme Court of the United States in denying the power to require an examination, under penalty of a dismissal of the case for refusal to submit to same, did not notice the influence which the federal statute had on the determination of the question by that court.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.
August 1.

1 *Chronic Postdiphtheritic Laryngeal Stenosis as a Cause of Persistent Intubation of the Larynx. Henry W. Berg.
2 *Two Cases of Congenital Elevation of the Shoulder, with a Review of the Reported Cases. Russell A. Hibbs and H. Correll-Loewensteln.
3 Life and Its Physical Basis. Axel E. Gibson.
4 *A Signal Test for Color-Blindness. Percy Fridenberg.

1. **Chronic Postdiphtheritic Laryngeal Stenosis.**—Berg's article gives the causes of prolonged intubation, the effects of defective tubes (too large in the swelling, or roughened in surface) in causing necrosis or pressure sores, the dangers of such conditions and the occurrence of autoextubation. The prevention of these pressure sores forms an important part of the treatment and depends on the selection of the proper sort of tubes and care in the technic in intubation and extubation. When the case has developed into a tube case we should see whether the stenosis is due to pressure sores or decubitus with swelling, to decubitus followed by cicatricial contracture or decubitus with paralysis of the vocal cords, or a combination of these. If cicatricial stenosis is present, persistent intubation with a tube of just the right size to pass through the strictured larynx without difficulty, but not to be forced out, is most apt to be successful, and the intubation is not to be done too frequently. The use of astringent ointments on the tubes, the author thinks, is hardly necessary, from his experience. It may take months or years before the patient can get altogether along without the tube. Cases of paralysis of the vocal cords due to pressure on the recurrent laryngeal nerve without cicatricial stricture, are best treated by intubation with either a larger tube than is usual for the age of the patient, or one with an increased swelling; this should be nearer the neck of the tube than is usually the case. For atresia of the larynx, surgical treatment is the only method.

2. **Congenital Elevation of the Shoulder.**—Hibbs and Loewenstein report two cases, and classify the conditions thus: "1. With a bony bridge between the scapula and vertebral column; 2, with absolute absence of one or two muscles forming the shoulder girdle; 3, cases with a long and turned over supraspinous portion of the scapula; and 4, cases without bony overgrowth, the scapula normal or smaller, with shorter or otherwise defective muscles." They refer to published cases according to their classes, and discuss the etiology of the anomaly. In the first of the cases reported, the defect seemed to be due to a triangular piece of bone continuous with the scapula and articulating with a pivot joint to the seventh cervical vertebra, due to epiphyseal overgrowth of developmental origin, starting early in fetal life. The second class of cases is due to congenital lack of one or two muscles. The third class is due to the curved and possibly enlarged condition of the supraspinous portion of the scapula, which is accounted for according to the Sprengel theory as the outcome of intra-uterine pressure due to a lack of amniotic fluid. The fourth class of cases is of obscure origin, and represents conditions that have not been sufficiently studied. Probably some of them are not truly congenital. In the first and third classes, the only treatment is to resect the bony bridge or bent forward piece of bone; in the second class, orthopedic appliances to press the shoulder down and substitute the missing depressors where required. The fourth class will probably have to be treated orthopedically, by apparatus, massage, exercise, electricity, and, in selected cases, by the knife.

4. **Color-Blindness.**—Fridenberg notices the defects of the Holmgren test and its advantages if supplemented by a proper lantern test. He describes a lantern which he has devised.

The Boston Medical and Surgical Journal.

July 30.

5 The Sources, Favoring Conditions and Prophylaxis of Malaria in Temperate Climates, with Special Reference to Massachusetts. (Shattuck Lecture.) Theobald Smith.
6 *Problems of Clinical Anatomy. Thomas Dwight.
7 *The Need of a Supplementary Lantern Test for the Proper Examination of Color Perception. Charles H. Williams.
8 Efforts to Abate the Mosquito Nuisance in Brookline. H. Lincoln Chase.

6. **Problems of Clinical Anatomy.**—Dwight calls attention to the fact that all people are not made alike; that there are variations of structure often not recognized during life, knowledge of which would have helped the medical practitioner, and especially the surgeon. The results of certain series of observations are also, he thinks, establishing the law that certain pathologic conditions have their origin in some peculiarity of development. He calls attention to certain special points, such as the paralysis of the muscles of the larynx, in the symptomatology of aneurism of the right subclavian artery. Nevertheless, this may not occur, owing to a deviation of the artery which arises from the region of the aorta and passes behind the esophagus to its destination. Here the inferior laryngeal nerve is not recurrent. He expects to find this arrangement at least once a year in the dissecting room. Another is the peculiarity of the aorta in severe Pott's disease, where it lies, as it were, half coiled around the spine. Still another anomaly is the fusion of the atlas with the occiput, the existence of new bones and fusion of others, etc.

7. **Color-Blindness.**—Williams describes the lantern he has devised to test color vision supplementary to the Holmgren test, the defects of which he recognizes.

Medical News, New York.

9 *Fetal, Congenital and Infantile Typhoid. John Lovett Morse.
10 *Some Cases of Prostatectomy, Observed After an Interval. Alexander B. Johnson.
11 Case of Bothriocephalus Latus in a Woman Immigrant, with Remarks on the Occurrence of this Parasite in America. William N. Berkeley.
12 Hernia. S. W. S. Toms.
13 Thiocol. J. Leffingwell Hatch.
14 *On the Presence of Specific Coagulins in the Tissues of Vertebrates and Evertebrates. Leo Loeb.
15 Pustulation and Its Accompanying Secondary Fever a Complication and Not an Essential Symptom of Smallpox. Jennie G. Drennan.

9. **Infantile Typhoid.**—See abstract in JOURNAL, vol. xl, April 11, 1903, p. 1018.

10. **Prostatectomy.**—Johnson operates by a perineal incision, with a second abdominal incision, the latter being utilized to afford access to the prevesical space, the fingers of the left hand inserted in this abdominal wound, making counter-pressure to the fingers of the right hand, working in the perineum. He makes a perineal incision, convexity forward, and, after separating the muscles surrounding the urethra from the anterior extremity of the sphincter ani, exposes the prostate by blunt dissection, using the sound in the urethra as a convenient guide. When the prostate is reached, it is pushed downward by the fingers of the left hand, into the perineum, and can generally be brought in sight. An incision is then made obliquely upward and outward through the capsule of each lateral lobe, and the enucleation accomplished by separating the capsule with the forefinger of the right hand. There is apt to be a tear of the urethra on one side or the other, and it is utilized for the drainage tube subsequently. He speaks particularly of the utility of the downward pressure from above in putting the prostatic plexus of veins on the stretch and thus preventing the bleeding. A suprapubic opening into the bladder is not advisable, and the infectious urine in the wound not at all advantageous. He reports cases observed at intervals of one or two years or more with good results; in all of them sexual power or desire has been diminished or lost.

14. **Specific Coagulins.**—Loeb found that the muscular tissues of various animals have a coagulating power on the blood of the same species. These coagulins are analogous to certain substances which are obtained through the process of immunization, namely, the agglutinins, precipitins, and lysins. The probability is not excluded that these coagulins may also act on other species, though less strongly. Each species of animal so far tested has specifically adapted means for preventing a dangerous loss of blood. The origin is probably of interest; it is not entirely explained by a selective process. The possibility of its being due to the lymph is excluded by the author as improbable, as a careful washing of the tissue does not diminish the influence of the tissue on coagulation, and he finds it can be definitely proven that the influence of a piece of muscle of a lobster is derived from the muscle itself.

16 *Appendicitis as an Incident in Development. Woods Hutchinson.
17 *Bradycardia as a Symptom. Roland G. Curtin.
18 A Study in Astigmatism. Arthur G. Bennett and J. C. Clemesha.
19 *The Teaching of Personal Hygiene. Arthur L. Pyle.
20 *An Ideal Method for Drainage in Cholecystostomy. Alois B. Graham.
21 A Case of Metastasis of Mumps to the Brain. H. E. Wright.

16. **Appendicitis.**—Hutchinson considers that Ochsner's method of treating appendicitis is simply a return to Nature's methods in the case, and while he was first inclined to doubt, the observation of the practice of one of his surgical confrères has convinced him of its excellence. He describes the embryologic development of the appendix, and its occurrence in the lower animals. Of course, the operation for the removal of the appendix, in the interval, is advisable, but he thinks that Ochsner's plan to help Nature in walling off the inflammation is the correct one.

17. **Bradycardia.**—Curtin notices the effects of bradycardia and conditions in which it has been observed, pointing out that it is so common a symptom and occurs in so widely different diseases that it can be of only small diagnostic value. In a constitution not undermined by disease, and with a gradual subsidence, it need not be considered a grave symptom. On the other hand, if associated with or caused by a depressing chronic condition, especially of the cardiovascular system, it becomes a very serious symptom. When accompanied by anginose symptoms, it is frequently followed by sudden death.

19. **Hygiene.**—See abstract in THE JOURNAL, vol. xl, p. 1528.

20. **Drainage in Cholecystostomy.**—Graham describes the method of drainage of the gall bladder after cholecystostomy, devised by Dr. George J. Cook, which is performed as follows:

> The drainage tube employed should be of large caliber and possess firm walls, so as to be not easily compressed. Its proximal end is firmly fixed in the gall bladder by a purse-string suture. Its distal end should not project more than one and one-half to two inches beyond the edges of the wound. To this end is firmly tied an extra large and extra thick condom or rubber sac. The gauze dressings are next applied; on these is placed the condom or rubber sac, and this is well surrounded and covered with cotton. All are retained in position by a binder bandage snugly adjusted. It can readily be seen that by this method we have produced an artificial gall bladder, and it lies in close proximity to the gall bladder which is to be drained. This so-called artificial gall bladder is removed once or twice every twenty-four hours, emptied, and thoroughly cleansed, after which it is again placed in position.

He claims for it the advantages of being ideal and complete, simple and easy of performance, cleanly, enables the patient to change position without assistance; the bile is collected in a pure state and can not become contaminated, and it enables one to study the influence of the so-called cholagogues on the bile secretion. It is so superior to Dr. Kehr's method that it is hardly comparable. His careful perusal of the literature, however, has failed to reveal previous mention of it.

22 *Remarks on Medical Instruction; a Plea for Greater Uniformity. N. R. Coleman.
23 *The Psychical Relations of Tuberculosis in Fact and Fiction. G. A. De Santos Saxe.
24 *The Death Rate of Pneumonia. Thomas J. Mays.
25 *Dhobie Itch. Charles F. Mason.
26 Complete Removal of the Left Vocal Cord for Malignant Disease; Presentation of the Patient. Walter F. Chappell.
27 Chronic Lymphatic Leucemia Complicated by Pneumonia. T. Stuart Hart.

28 *An Improvised Method of Operating for Varicocele. Lucien Lofton.

22. **Medical Instruction.**—Coleman's address is in the line of his former address published in THE JOURNAL, vol. xl, p. 375, Feb. 7, 1903, but with more special reference to the medical curriculum.

23. **Tuberculosis.**—Saxe's article is to be continued. He reviews the characteristics of tuberculosis as given in literature, and in medical literature also, the consumptive type of insanity, the loss of self-control and increase of susceptibility to external mental influences, the variability of temper, and the alleged effect of the disease on the sexual instinct.

24. **Pneumonia.**—The alleged increase of mortality from pneumonia is noticed by Mays, who gives figures to show the ratio of deaths in various cities from pneumonia, tuberculosis and heart disease. He says:

In summing up the results of this investigation the following points seem to be fairly well established: First, there is no good reason for believing that pneumonia has gradually sprung into such prominence as to cause present or future alarm; for its highest death rate occurred before 1896, and since that time it has declined 21.17 per cent. Compared with heart diseases as a death menace, if such a term is permissible, pneumonia ranks rather low; for, in Chicago, the latter increased 350 per cent., and the former 450 per cent. in forty-two years. In the District of Columbia there is a marked decline in the pneumonia rate during the twenty-six years, while the deaths from heart disease increased 105 per cent. in the same time. In New Jersey, during twenty-three years, the deaths from pneumonia increased 30.95 per cent. and from heart diseases 55.55 per cent. In the composite chart the total increase of pneumonia deaths is not quite 10 per cent., while those from heart diseases increased 85.85 per cent.

Second, that in a number of the above-named localities the phthisis rate diminished from the beginning of the record; that there is a reduction in all of them in this respect from the early eighties to 1898, and that from the latter point of 1902 there is a general net increase. Thus, Philadelphia, St. Louis, the District of Columbia, Baltimore, Louisville, San Francisco and Rhode Island give a total increase of 117.17 per cent.; New York a decrease of 4.15 per cent., while Chicago, Buffalo, Richmond, Reading, New Jersey neither increase nor decrease, leaving, therefore, a net phthisical increase of 113.02 per cent. for the last five years, or between 1898 and 1902.

Third, that the natural average decrease in the death rate of phthisis is between 2 and 3 per cent. a year. This is shown in the composite chart, and in all the other charts in which a persistent decline occurred for a number of years in succession.

On the whole, we may, therefore, conclude that deaths from pneumonia are decreasing; that deaths from disease of the heart are increasing, and that deaths from phthisis decreased until five years ago, but have markedly increased since that time.

25. **Dhobie Itch.**—There are at least three types of infections known as dhobie itch, according to Mason; two of them mycotic, due to *Microsporon minutisimum* and the trichophyton, and one bacterial-pemphigus contagiosus. He says that the disease has been introduced into this country by soldiers returning from tropical service, and will probably become more prominent, especially where washing is not done by boiling. The prognosis will depend on the disease, whether mycotic or bacterial, and he describes pemphigus contagiosus, the treatment of which consists of thorough cleanliness of the parts and of the underclothes, with a twice daily sponging with a 1-1,000 solution of mercury bichlorid, followed when dry by a powder of equal parts of zinc oxid, boric acid and starch. If the mycotic dhobie is found, tincture of iodin, glacial acetic acid, 5 per cent. salicylic acid ointment, and 1 to 500 alcoholic solution of corrosive sublimate, would be effective in the order named.

28. **Varicocele.**—The method adopted by Lofton for this condition is the needling application of the ligation plan, and is described as follows:

The testicular case is prepared for action in the usual surgical manner. The patient is permitted to assume the semi-recumbent posture, when the scrotum is grasped with the left hand, the index finger and thumb separating the vas and the spermatic artery, i. e., placing them on the anterior border of the testicle, while the pampiniform plexus is brought well up against the anterior and upper walls of the bag, and held there firmly. With an ordinary curved surgeon's needle, three inches in length, armed with a double strand of No. 2 fiddle string, the pouch is pierced at the seat of election and the mass transfixed: the needle being curved at an angle of forty-five degrees, penetrates the opposite inner wall of the scrotum, but does not perforate it. With the point of the left index finger the needle is guided so as to slip along the inner wall of the bag, making a half circuit of the interior lining and over and above the transfixed veins, and is brought out at the original puncture and securely tied to the dangling ends of the external ligature. Caution must be observed in drawing the mass of veins well up against the inside anterior wall of the scrotum. This procedure, if it is thought necessary, may, at the same sitting, be duplicated from one to three times, at whatever points the surgeon's judgment may dictate. If you are sure you have separated the spermatic cord and artery from the general mass you may tie firmly at once; if not, gradual tightening is advised, as this will indicate the condition of affairs. The tying of the cord and artery with the veins is a mistake that some good men have made, but, with ordinary precaution, it should not occur. However, when this is done, great pain radiating from the lumbar region to the testicle on the affected side, and even on the penis, immediately sets in, and if not remedied, atrophy of the testicle will follow.

There is only one opening made in the scrotum and, when secondary inflammation sets in, the mass should be securely welded to the anterior walls. The patient can continue at his business without interruption. He has not had any severe inflammation or pain follow the procedure or any elevation of temperature in his cases. A well-fitting suspensory, of course, is advised for some weeks, and the bowels and kidneys should be in a healthy condition. Recovery follows on an average in from twenty-five to thirty days, and complete atrophy of the veins in about six months.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal, London.

July 25.

1 *Remarks on Ectopic Gestation and the Conditions Favorable for Its Advance to the Full term. John Ward Cousins.
2 A Case of Puerperal Eclampsia. Robert McDowell. With remarks by Professor Byers.
3 *On Influenzal Orchitis, with Three Cases. R. Clement Lucas.
4 The Causes of Acute Abdominal Pain in the Healthy, Exclusive of Traumatism. J. Lynn Thomas.
5 Hernia of the Bladder as a Complication of Inguinal Hernia. G. B. Ferguson.
6 Further Observations on Alcoholic and Arsenical Neuritis. Ernest Septimus Reynolds.
7 A Case of Ankylostomiasis in Scotland. Ralph Stockman.
8 *Treatment of Atrophic Retina with Retinal Extract. Robert W. Doyne.
9 Two Cases of Fracture of the Base of the Skull, Which Recovered After Venesection. Stephen Paget.
10 The Buried Unabsorbable Ligature and Its Sequelæ. C. Hamilton Whiteford.
11 The Treatment of Hydrocele by the Method of Seton. A. A. Scot Skirving.

1. **Ectopic Gestation.**—The conditions favorable for carriage of the fetus to full term in ectopic gestation, are given by Cousins, as, first, early continuous mobility of the ovum; second, slow subperitoneal expansion of the sac; third, absence of urgent symptoms indicating intraperitoneal or extraperitoneal rupture; fourth, the early ascent of the fetus toward the abdominal cavity; and fifth, the lateral position of the placenta in relation to the gestation sac and its upward expansion and elongation. He discusses the etiology of ectopic gestation. He thinks that while there are many unsettled points, the following conditions may be taken as a basis for further investigation: first, the fertilization of the ovum sometimes occurs within a tube in which the lumen has been distorted by chronic changes within or around it; second, that in addition to some form of mechanical obstruction, the tubal mucosa may be changed under genetic influence into decidual tissue, and that this structural change is necessary for the vital attachment of the embryo.

3. **Influenzal Orchitis.**—From cases he reports, Lucas assumes that often the inflammation of the testis may follow influenza close on the fever; that after one is recovered, the other may be attacked; second, that when there is an epidemic of influenza in the neighborhood, sporadic cases probably occur as the result of the influenzal germ, though the direct connection may be difficult to trace.

8. **Atrophia Retinae.**—Doyne has experimented with retinal extract in cases of retinal atrophy, on the theory of charging the blood more richly with the retinal constituents, and thus compensating for a lack of the usual nutrition. His results have been such as make him conclude that there is a certain amount of benefit in this treatment in cases of retinal, but not optic nerve, atrophy.

15 Roentgen Rays in the Diagnosis of Lung Disease. David Lawson and R. Hill Crombie.
16 Some Further Improvements in the Procedures for Testing and Judging by the Naked Eye of the Agglutinating and Bacteriolytic Effects Exerted by the Sera of Patients Suffering from, or Preventively Inoculated Against, Typhoid Fever, Malta Fever and Tuberculous Affections. A. E. Wright.
17 Observations on Mastication. Harry Campbell.
18 The Conservative Treatment of Lesions of the Uterine Appendages. George Granville Bantock.
19 Have the Locality and Surroundings an Influence on the Recurrence of Malignant Disease After Operation? D'Arcy Power.
20 Hepatectomy for the Removal of Riedel's Lobe. Charles Barrett Lockwood.
21 Enzymes in Tumors. Arthur Harden and Allan MacFadyen.
22 The New Royal Victoria Hospital, Belfast. Prof. J. W. Byers.

12. **Local Analgesia.**—The difficulty of applying in practice the discovery of Corning, that a local anesthetic introduced to any part of the nerve trunk would abolish its sensation to its minutest termination, is first noted. Barker was led by this to adopt the principle laid down by Braun of Leipsic, that anything that retards or diminishes the circulation of the blood in the part, enhances the power of the analgesic agent, and followed Braun's suggestion of investigating further whether the diminution produced by the injection of adrenalin would not also have this effect. His results were good. He gives the proportions which he used; two grains B-eucain with ten grains of chlorid of sodium, added to 100 cubic centimeters of boiling distilled water, then a cubic centimeter of solution of adrenalin was added when the fluid had cooled. The difficulty of keeping the solution of adrenalin perfect, is mentioned, and he suggests that this preparation be put up in thin glass capsules like those of nitrite of amyl, which can be broken at the time needed. He has operated by this method in a number of cases of hernia and tumor extraction, varicose veins, skin grafting, abscesses, etc., and considers the success of the local anesthesia thus applied very marked.

13. **Pulmonary Tuberculosis.**—Bulstrode gives here in tabulated statement the statistics of tuberculosis in various countries and cities, Prussia, France, Denmark, Switzerland, etc., showing that in all, except it may be in France, a very marked diminution in the phthisis mortality.

14. **The Susceptibility of Criminals to Atmospheric Changes.**—East, a medical officer of the convict prison at Portland, has studied the effect of atmospheric changes in criminals under his charge. Normal individuals are markedly affected by atmospheric changes, but he finds that criminals are practically insensible to their influence. The facts seem to confirm the view that criminals are less susceptible to external impressions than are normal individuals.

27 (No. 51.) *Epilepsie menstruelle traitée par la transplantation ovarienne. Ibid.

27. **Operation for Epilepsy with Transplantation of Part of the Ovaries.**—Brennan operated last November on a young woman of 19 who had suffered from epileptic seizures since her first menstruation at 8 years of age. They recurred sometimes as often as three a day, and usually about six to fourteen a month, but seemed to be restricted to the menstrual period. No clinical lesion could be discovered, and the family history was good, the patient living in a Vermont town in easy circumstances. After failure of all other measures and loss of 40 pounds in weight during the last few months, Brennan removed both ovaries. A piece of the left ovary the size of a bean was transplanted in the fundus of the uterus. There was a very severe seizure the next day, but that was the last, and to date, June, 1903, there has been no recurrence nor any symptoms that might be attributed to the artificial menopause, except that after exceptional fatigue, on five or six occasions, there has been a slight nervous crisis.

64 Ueber die Operation der Cholecystitis acuta infectiosa im akuten Stadium. W. Körte.

35. **Radical Treatment of Invagination of Intestines.**—Eiselsberg's experience includes 13 cases of invagination, 3 acute, 3 subacute and 7 chronic. The cause of the invagination was polyposis in 3 cases and a cicatrix or neoplasm in 4, while in 6 there was merely an abnormally long mesentery. He advises cautious attempts to reduce the invagination in order to determine how large a part of the intestine is involved. In acute cases or in much debilitated subjects the intervention should be restricted to this alone. Under other circumstances he advocates total resection to prevent recurrence. He succeeded in reducing the invagination in 5 cases and partially in 3 out of 12 in which he attempted it, and 9 of the 12 in which he performed total resection have been definitely cured. He absolutely rejects enteroanastomosis for this purpose, as also an artificial anus.

36. **Carcinomata of Intestines.**—Mikulicz's article is scarcely adapted for an abstract, as he reviews his extensive experience in detail.

40. **Treatment of Cavities in the Tibia.**—Mangoldt has found that a cavity in the tibia gradually becomes smaller and finally becomes entirely obliterated when it is lined with a flap of skin and periosteum. Small cavities can thus be lined with a tongue-shaped flap with a broad base fitted into the cleaned and leveled cavity, but larger ones require a flap of skin and periosteum drawn down from the margin of the wound after undermining it enough. A rapid and durable covering for a large cavity can be obtained with Thiersch flaps or Mangoldt's method of sowing epithelium. Cavities in the epiphysis may be lined with a turned-over flap of skin and periosteum. The cavities lined with transplanted flaps heal perfectly, but do not grow smaller as occurs with the pedunculated flaps. He describes a dozen cases in detail. In 2 the cavity became spontaneously obliterated after it had been lined with a pedunculated flap of periosteum taken from under the skin.

47. **Pustula Maligna.**—Hoelscher found pure cultures of staphylococci in 2 out of 7 cases of pustula maligna. All the patients recovered.

49. **Development of Carcinoma on Inflammatory Processes.**—De Ruyter reports a case of two carcinomata developing on the nasal mucous membrane consecutive to an old empyema of the antrum of Highmore. In a second case the carcinoma developed in an inflamed and cystically degenerated mamma, and in the third on the basis of an old perityphlitis.

51. **Collargol in Septic Processes.**—Credé reiterates his recommendation of collargol for all septic processes. In mild or moderately severe cases it can be used in inunctions, but in the severe and urgent it should be applied from the start in intravenous injections.

52. **Draining of the Hepatic Duct.**—Kehr's views have been presented in The Journal from time to time, and his address at Washington on this subject was summarized on page 1598 of the last volume. This article is a detailed statement of the technic, operations and results at his clinic, a total of 25 cases of cholelithiasis treated by drainage of the biliary passages.

56. **Winkelmann's Operation for Hydrocele.**—Klaussner has collected 104 cases of hydrocele in the literature treated by Winkelmann's operation. There has been recurrence in 2 out of this number. He has performed the operation himself in 35 cases, and recommends it for all uncomplicated ones in which the tunica vaginalis is not too rigid to be turned over in this way.

57. **Surgery of Larynx, Trachea, Etc.**—Gluck has been a pioneer in the extirpation of the larynx and pharynx, and his results have been very fine. He describes in detail his technic, apparatus for closing fistulæ, for improving phonation and for substituting parts of the defects in these organs. Only one has died out of his 22 patients whose larynx he has extirpated.

62. **Influence of Vitality of Tissues on Toxic Action of Local Anesthetics.**—Braun's experiments and conclusions are along lines almost identical with those of Barker, No. 12 above. Barker refers to Braun.

74 Records of Strasburg Midwives' Training School. R. Landau. Eine Urkunde der Str. Hebammenlehranstalt.

70. **"Modorra."**—Peypers has been comparing the historic accounts of the epidemics of "modorra" in the Canary Islands in 1494, and the two later centuries. He thinks that the word was used to express bubonic plague and not sleeping sickness, as some have recently asserted.

71. **Attempt at Identification of the Medicinal Plants Mentioned by Dioscorides.**—Bonnet reproduces some of the drawings on the ancient Greek MS. and establishes the identity of a large number of the plants whose medicinal virtues are described. Some of the drawings are reproduced.

73. **Indications of the Haschish-Vice in the Old Testament.**—Creighton gives a new rendering of certain words in the Old Testament, endeavoring to prove that the disreputable intoxicant drug of the east, haschish, was known and used then, and that the vice was recognized as such and attempts at regulation made. It did not come under the head of a drink but of food, and he argues to prove that it was the secret of Jonathan's and Samson's strength and of Saul's madness. Samson's "strength" collapses, just as Saul's "courage" fails, the stimulant having lost its power, and being followed by hebetude. Creighton thinks that the "grass" on which Nebuchadnezzar fed was this same drug. He was in fact first interested in the subject by noting the similarity between the ordinary Arabic word for grass, hachach, and haschish, the term for Indian hemp. He concludes by suggesting that the first chapter of Ezekiel, with its phantasmagoria of composite creatures, wheels, and of brilliant play of colors is unintelligible from any point of view except that of the subjective visual perceptions induced by haschish. He adds that this chapter caused long hesitation before the book of Ezekiel was included in the accepted text of the Bible. The article is in English.

75. **Spleen Abscess.**—The diagnosis is assured if a fluctuating tumor can be palpated under the costal arch, especially if accompanied by pyemic fever and local pains. To relieve the pain in the spleen the patients may assume a characteristic attitude, lying on the back with the left thigh flexed. The prognosis is grave, although recovery has followed prompt surgical intervention in some cases. In the typical one described the abscess was of tuberculous origin, as also the peribronchial and mesenteric glandular lesions. Less than a dozen cases are on record of abscess of the spleen, and only 3 recovered. Some were consecutive to typhoid or malaria, and one to articular rheumatism. Four of the patients were women.

76. **Retention of the Chlorids in Pneumonia.**—Santini called attention in 1902 to the hypochloruria observed in the course of pneumonia and has since established that it is a constant phenomenon in all acute infections. (The diagnostic importance of the retention of chlorids has recently been emphatically proclaimed from Senator's clinic, as quoted at length on page 140 of The Journal.) In a patient under observation for some time on account of mitral stenosis, the elimination of chlorids was constantly 8 to 10 gm. a day. An attack of pneumonia supervened, and the first day the chlorids were 9.41 gm., and the next, only 1.17 gm. In another patient the onset of an acute infection caused the chlorids to drop from 14.47 gm. the day before to 6.81 gm. the first, and 2.19 gm. the second day. In another patient two attacks of pneumonia occurred while under observation, and in both the same sudden drop in the chlorids was noted in twenty-four to forty-eight hours. From the clinical study of 50 patients with pneumonia he states that

this constant hypochloruria ranges from a daily minimum of .5 gm. to 6-7 gm., but does not seem to bear any relation to the extent of the pneumonic focus, nor the height of the fever. When salt is ingested by normal subjects the proportion eliminated in excess approximates the amount ingested, but this does not occur in case of hypochloruria. Even when a pneumonia patient took as much as 24 gm. of salt during the day, the percentage in the urine was only slightly increased, not at all in proportion to the quantity ingested. Santini concludes from his experiments and the arguments he presents that the quotient of the alkaline-mineral chlorid remains invariable in the tissues in pneumonia as in health, or may be a trifle lower in the former. During the infectious process the chlorin enters into combination with organic substances abnormally produced, and the product is impermeable for the kidneys. Even in physiologic conditions, while a constant proportion of the chlorin is found in the tissues in the form of an alkaline-mineral chlorid, another part is found in combination with organic principles. The retained chlorin can be readily found in the desiccated blood and tissues by mixing them with a 2.5 per cent. solution of caustic soda and setting aside for a time, occasionally shaking the vessel, then proceeding as usual for its determination.

77. **Treatment of Echinococcus Cysts in Liver with Injections of Sublimate.**—Pirrone gives the particulars of 3 cases of an echinococcus cyst in the liver completely and rapidly cured by aspiration of a small portion—about 10 c.c.—of the contents of the cyst, and injection through the needle before its removal of a smaller amount of a 1 per cent. solution of sublimate—about 2 c.c.—repeating the procedure in a week. Exploratory puncture and aspiration a month later were entirely negative, and the experiences in these cases have been duplicated in a large number of others. The conditions for success are that the contents of the cyst are sterile, that the cavity is single, that the lesion has not lasted so long that the walls of the cyst have become rigid and thus unable to retract, and lastly, that the cavity is not too extensive. It is important to apply a constricting bandage around the abdomen below the liver before making the puncture, and afterward to place an ice bag over the liver for twenty-four hours, withhold food for eighteen hours at least, and keep the patient immovable on his back in bed. The death of the parasites is indicated by leucocytosis in the fluid obtained by puncture and the presence of numerous hooks which become detached from the wall. The fluid first aspirated contains few, if any, of these hooklets. The liver is usually hypertrophied to compensate for the loss of the portion invaded by the cyst, and although not degenerated elsewhere, yet the organ generally remains enlarged after recovery. Pirrone styles this Baccelli method of treating echinococcus cysts "a positive and important conquest in the field of therapeutics." By removing only a small amount of the contents of the cyst the dangers from abrupt changes in pressure are avoided, and Nature attends to the gradual and safe absorption of the remainder as soon as the parasites are killed by the sublimate injection. The reaction is slight, possibly a little pain in the corresponding shoulder, and slight fever the day after the injection, not more than 38.5 C. The symptoms then all gradually subside.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, July 25, 1903:

Daywalt, George W., contract surgeon, is relieved from further duty at Fort Schuyler and from temporary duty at Fort Levett, and will proceed to Fort St. Philip for duty, to relieve Contract Surgeon Frederick Hadra, who will proceed to his home, San Antonio, Texas, for annulment of contract.

Gregory, Verdo B., contract surgeon, now at Vancouver Barracks, is relieved from further duty in the Department of the Columbia, and will proceed to his home, Bowers, Wis., for annulment of contract.

McCulloch, Jr., Champe C., captain and asst.-surgeon, is granted leave for ten days.

Roberts, William, first lieut. and asst.-surgeon, is relieved from treatment at the Army and Navy General Hospital, Hot Springs, Ark., and will return to his station at Fort Brady.

Reno, William W., first lieut. and asst.-surgeon, now at San Francisco, is relieved from further duty in the Division of the Philippines, and will proceed to Fort Crook for duty.

Winter, Francis A., captain and asst.-surgeon, is granted an extension of leave for twenty days.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 1, 1903:

Medical Director M. H. Simons, commissioned medical director from June 9, 1903.

Drs. S. L. Scott, T. N. Pease and F. G. Abeken, appointed assistant surgeons from July 10, 1903.

Hospital Steward E. May, appointed pharmacist from March 28, 1903.

Hospital Steward T. N. Phillips, appointed pharmacist from June 8, 1903.

P. A. Surgeons E. M. Blackwell and G. F. Freeman, commissioned as such from June 7, 1903.

Asst.-Surgeon C. E. Ryder, ordered to the Naval Hospital, Chelsea, Mass.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Aug. 1, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, June 18-25, 4 cases.
California: Los Angeles, July 11-18, 1 case; San Francisco, July 12-19, 5 cases.
Illinois: Belleville, July 11-25, 3 cases; Chicago, July 15-25, 1 case, 1 death.
Indiana: Indianapolis, July 18-25, 1 death; South Bend, July 18-25, 1 case.
Louisiana: New Orleans, July 18-25, 3 cases.
Massachusetts: Fall River, July 18-25, 7 cases.
Michigan: Detroit, July 18-25, 6 cases, 3 deaths; Grand Rapids, July 18-25, 1 case; Port Huron, July 18-25, 2 cases.
Mississippi: Natchez, July 11-18, 1 case.
Missouri: St. Louis, July 18-25, 2 cases.
New Hampshire: Manchester, July 18-25, 5 cases.
New York: Rochester, July 14-21, 1 case.
Ohio: Cincinnati, July 17-24, 3 cases; Dayton, July 18-25, 5 cases; Toledo, July 18-25, 2 cases.
Pennsylvania: Norristown, July 18-25, 3 cases, imported from Philadelphia; Pittsburg, July 18-25, 14 cases, 6 deaths; Scranton, July 18-25, 2 cases, 1 death.
South Carolina: Charleston, July 18-25, 1 case; Greenville, July 11-18, 4 cases.
Utah: Salt Lake City, July 18-25, 2 cases.
Washington: Tacoma, July 13-20, 1 case.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, May 1-31, 11 deaths.
Austria: Prague, July 4-11, 5 cases.
Belgium: Antwerp, July 4-11, 3 cases, 3 deaths; Brussels, July 4-11, 3 deaths.
Brazil: Rio de Janeiro, June 14-28, 12 deaths.
China: Hongkong, May 31-June 13, 3 cases, 1 death.
Colombia: Bocas del Toro, July 7-14, 5 cases, 1 death.
France: Paris, June 27-July 4, 1 death.
Great Britain: Dublin, July 4-11, 5 cases; Dundee, July 6-13, 3 cases; Edinburgh, July 4-11, 1 case; Leeds, July 11-18, 6 cases; Liverpool, to July 18, 13 cases, 3 deaths; London, June 20-July 11, 42 cases; Manchester, July 4-11, 2 cases; Newcastle-on-Tyne, July 4-11, 1 case; Nottingham, July 4-11, 10 cases; Sheffield, July 11-18, 1 case.
Japan: Kobo, June 13-20, 1 death; Nagasaki, June 11-20, 1 case.
Mexico: City of Mexico, July 5-19, 31 cases, 25 deaths; Tampico, July 11-18, 2 cases; Vera Cruz, July 4-11, 1 case, imported.
Russia: Moscow, June 27-July 4, 5 cases, 4 deaths.
Turkey: Constantinople, July 5-12, 2 deaths.
Uruguay: Montevideo, May 31-June 20, 4 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, June 14-23, 4 deaths.
Costa Rica: Limon, July 8-16, 2 cases, 1 death.
Mexico: Altamira, July 14, present; Motzorongo, July 13, present; Progreso, July 12-19, 3 cases, 1 death; Tampico, July 11-18, 45 deaths; Tierra Blanca, July 13, present; Vera Cruz, July 11-18, 43 cases, 13 deaths; Zongolica, July 13, 5 cases.

CHOLERA.

China: Amoy, July 22, present; Hongkong, June 6-13, 1 death.
India: Calcutta, June 20-27, 30 deaths.
Straits Settlements: Singapore, June 6-13, 8 cases.
Turkey in Asia: Catana, May 24-June 6, 10 deaths; Damascus, June 6-20, 6 deaths in province; Luma, June 2, 2 deaths; Zibdani, May 31, 1 death.

PLAGUE—UNITED STATES.

California: San Francisco, June 15, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, May 31-June 6, 15 cases, 4 deaths; Natal, May 16-23, 2 cases.
Australia: Sydney, June 13, 1 case.
Brazil: Rio de Janeiro, June 14-20, 5 deaths.
China: Hongkong, May 31-June 13, 256 cases, 172 deaths.
Egypt: Alexandria, June 20-27, 5 cases, 4 deaths; Port Said, June 20-27, 2 cases, 1 death; other localities, June 20-27, 2 deaths.
India: Calcutta, June 20-27, 14 deaths; Karachi, June 14-28, 14 cases, 11 deaths.
New Caledonia: July 26, present.

THE APPARENT IMMUNIZING VALUE OF ATTENUATED TUBERCLE BACILLI.*

E. A. DE SCHWEINITZ, M.D.

Director of Biochemic Laboratory, Bureau of Animal Industry, Department of Agriculture, and Dean, the Columbian Medical School.

WASHINGTON, D. C.

The recent attention which has been drawn to the difference in virulence of tubercle bacilli from various animals, and the publication by Behring of the production of immunity to tuberculosis in cattle by the use of tubercle bacilli of low virulence, have suggested that if perhaps a little more attention had been given to some work published in December, 1894, there would have been less tendency in some quarters, at any rate, to assume an absolute difference between tubercle bacilli obtained from men and those obtained from cattle. The published works of the writer and Dorset and Schroeder, Ravenel, Nocard and that of others, have shown so conclusively that it is possible to obtain tubercle bacilli, sometimes from the sputum of adults and frequently from intestinal lesions in children, which will produce tuberculosis in cattle when the latter are inoculated subcutaneously, that it seems now almost a waste of time to discuss a question which has been so positively proved. Considering further the numerous cases of accidental infection with bovine tuberculous material, and also that monkeys are more readily infected with bovine tuberculosis than with human tuberculosis, and it is well known that monkeys are more closely allied to man than any other animal, the possibility of the intercommunicability of bovine and human tuberculosis has been well established. The fact, further, that tubercle bacilli as well as other bacilli become more or less attenuated, depending on their growth on artificial media outside of the animal body or on their cultivation within the animal body, or in other words, the fact that they are easily influenced like other plants, by changes in soil and climate, has also been well proven by ourselves and others.

Our work, published in 1894,[1] was the first to show that guinea-pigs that had received large doses of attenuated human tubercle bacilli, those bacilli that had largely lost their virulence or power of producing disease, were rendered resistant and immune to subsequent inoculation with tuberculous material of bovine origin. Futher, in 1894-5-6-7-8, cattle and various other large and small animals were injected with frequent doses of attenuated tubercle bacilli and in some cases subsequently tested by inoculation with bovine tuberculous material. While the earlier works on the effect of large doses and the apparent immunizing value of attenuated human cultures on cattle were reported in 1896, Bulletin No. 13, Bureau of Animal Industry, and in the Proceedings of the Association of American Physicians, 1897, the results of the practical tests on some of these animals with tuberculous material have never been recorded, but may be of interest now. The practical treatment of these animals was made for me at the Experiment Station of the Bureau of Animal Industry by Dr. E. C. Schroeder.

In one of our earlier experiments begun in 1894, an old cow, 285, from a tuberculous herd, which on physical examination appeared to be clearly tuberculous, was given large injections of tuberculin, subcutaneously. The first dose used was 25 c.c. and the amounts were gradually increased so that between August, 1895, and October, 1897, when the animal was killed, it had received altogether 19,500 c.c. of tuberculin, as much as 1,500 c.c. being given at one dose. After four months' treatment with tuberculin the cow seemed to improve considerably. This apparent improvement, however, did not persist and the autopsy, when made in 1897, showed a most generalized tuberculosis, all stages of the disease being apparent. If the treatment with tuberculin had any beneficial effects the disease was so far advanced when the treatment was begun that no practical benefit could be secured.

IMMUNITY TESTS ON CATTLE.

On July 26, 1894, cow 217 received an injection in the jugular vein of 16 c.c. of a suspension of an attenuated human tubercle culture then in the 17th generation. This injection produced a large swelling at the seat of inoculation, but no other evidence of tuberculosis was noted.

On Nov. 28, 1894, this same animal received an abdominal injection of 6 c.c. of the 23d generation of attenuated culture. On Jan. 25, 1895, it received an intrathoracic injection of 6 c.c. of unfiltered culture of the 26th generation. On March 5, 1895, it received an injection into the right side of the chest of 16 c.c. of the 33d generation of a tubercle culture. Between April, 1895, and July, 1897, the animal received subcutaneous injections of attenuated tubercle culture, as much as 2,000 c.c. being given at a single injection. Altogether, therefore, it had received one intravenous, two intrathoracic, two abdominal and thirty-nine subcutaneous injections of attenuated tubercle culture. As the animal appeared to be in good health and well on Feb. 22,

1 Medical News.

1898, it received an injection into the thoracic cavity of 10 c.c. of a turbid triturate of a tuberculous gland obtained from a cow. This gland contained many virulent bacilli, as proved by inoculation tests. On Sept. 20, 1898, this cow was killed, and postmortem examination showed it to be free from disease, indicating, therefore, that neither the attenuated human culture nor the bovine material had produced tuberculosis.

Another cow, 297, the offspring of the tuberculin cow just referred to, 285, was tested with tuberculin on Nov. 19 and 20, 1894, and found free from disease. On Nov. 24, 1894, it received an injection in the abdominal cavity of 6 c.c. of the 23d generation of a tubercle culture. The temperature as taken for ten days following the injection seemed to indicate no disease. Between Jan. 25, 1895, and July 25, 1895, it received five subcutaneous injections of attenuated tubercle culture, about 250 c.c. being given altogether. In August, 1895, it received an injection of a bovine culture. Beginning again Dec. 2, 1895, it received large subcutaneous injections of attenuated tubercle culture, about 13,500 c.c. of the material being given altogether. On Feb. 22, 1898, at the same time that 217 was inoculated, it received an intrathoracic injection of some of the same tuberculous material as that given to 217. Killed on Sept. 20, 1898, when apparently in good condition, the autopsy showed a few tubercular nodules in the udder, while the superficial lymph glands, liver, kidneys and spleen were normal. There were, however, some large tubercular masses on the pleura. The tubercular lesions appeared to have come from the first inoculation with bovine material.

In April, 1896, two calves were inoculated with smaller doses of attenuated tubercle culture, subcutaneously, two animals with serum from cow 285, which in its turn, as reported, had received large doses of tuberculin, and two animals were reserved as checks. These calves subsequently tested with bovine tuberculous material did not show the same amount of resistance as did those first inoculated. One of the calves which had received preventive inoculations of the serum from cow 285 seemed to possess immunity. So far as the records of the check inoculated with bovine material show (these latter records are unfortunately incomplete) the check contracted tuberculosis from which it died in September, 1896, while the preventively inoculated animals had shown considerable resistance. The established immunity was not as good as that obtained in the first experiments. In the first tests several intravenous inoculations, as well as subcutaneous, were made. In the second set only a small number of subcutaneous inoculations were made.

These experiments on cattle considered in connection with those on guinea-pigs showed that as it was possible to vaccinate against bovine tuberculosis by means of tubercle bacilli of human origin, then we are simply dealing with tubercle bacilli of varying degrees of virulence, and not tubercle bacilli that are really different from each other. The readiness, as we have shown, with which not only human but, as may be seen from the records attached, also bovine tubercle bacilli may be attenuated, and the ease with which, according to Nocard, avian tubercle bacilli may be converted into those of a mammalian character, all go to prove the intimate relationship of bacilli obtained from various sources.

Steer 242 was drenched with bovine tuberculous material on Jan. 10, 11, 13 and 21, 1902. On February 17, 18 and 26 of the same year, tested with tuberculin, a positive reaction was given. On October 6, about nine months after the first drenching, this animal was killed. A few small foci of a tuberculous character were found in the mediastinal and in the lymph glands at the entrance of the thorax; otherwise no evidence of tuberculosis.

On Nov. 2, 1901, bull 223 was inoculated subcutaneously with 10 c.c. of bovine culture No. 3 (Smith). On Jan. 21, 1902, and April 18, 1902, reactions after tuberculin injections were noted. On Oct. 2, 1902, when the animal was killed, its general condition was excellent. At the seat of inoculation there was a patch of induration about six inches in diameter in which were imbedded small abscesses containing a soft, cheesy material. The shoulder glands on the side of infection, both deep and superficial, were enlarged and sprinkled with necrotic foci. The mediastinal glands contained numerous necrotic foci. No other lesions of any kind were present.

This animal showed very much less tuberculosis than that found after six weeks in a calf which received, subcutaneously, injections of material from tuberculous cultures isolated from children. Compared with the record of another heifer, 284, which had been inoculated with a different virulent bovine culture (a culture that had been isolated from a spontaneous case of disease occurring at the Experiment Station), and which showed after eight weeks very generalized tuberculosis, it is very evident that the bovine germ by cultivation loses in violence and in ability to produce disease just as well as the human bacillus. It becomes attenuated. This is another strong point and emphasizes the influences of environment on the virulence of bovine as well as human bacilli.

Our earlier work and results in this connection have therefore simply been confirmed by the recent experiments of MacFadyean, Behring, Pearson and Gilliland and others.

DISCUSSION.

DR. L. HEKTOEN, Chicago—Did I understand the author to mean by attenuated bacilli those that have been cultivated artificially for some considerable time?

DR. M. DORSET, Washington, D. C.—This culture referred to is one which lost its virulence after having been cultivated for several years and one which will not kill guinea-pigs even in large doses.

DR. JOSEPH MCFARLAND, Philadelphia—Is that a peculiarity of this bacillus or is the same true of all bacilli? Do they all become attenuated?

DR. M. DORSET, Washington, D. C.—This particular human culture is the most attenuated form we have. We have some human tubercle bacilli that have been growing for ten years without passage through an animal, and they are still quite virulent for guinea-pigs. This particular culture does seem to be an exception.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.—I would like to ask the gentlemen present if it has been their experience that tubercle bacilli become attenuated after having been grown for many generations?

DR. JOSEPH MCFARLAND, Philadelphia—I brought back with me from Berlin in 1895 a tubercle bacillus that had been isolated by Koch many years ago, and I kept it growing for more than five years. At the end of that time it seemed to have retained its virulence. I never went through any quantitative method of determining this, but relatively its virulence did not seem to be diminished. Unfortunately I lost the germ and could not continue the experiment.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.—In 1888, when I was a student in Koch's laboratory, Professor Fraenkel gave me a culture of the tubercle bacillus which he said was the

112th generation of one of the first cultures made by Professor Koch in 1882. I used that germ and its descendants in experiments on guinea-pigs and rabbits and it retained its virulence until about 1896. During the interval between 1888 and 1896 no year passed in which I did not inoculate animals with this germ, and in every case it was found to be virulent. In 1896 it began to lose its virulency for guinea-pigs, and soon ceased to have any effect even in large doses. Two years ago I sent to Dr. Lartigau a culture of this germ and a few weeks ago I had a letter from Dr. Baldwin of Saranac, saying that he had obtained the culture from Dr. Prudden and had experimented with it and that his experiments had confirmed my statements. The germ has completely lost its virulence so far as guinea-pigs were concerned.

NEW PHYSIOLOGIC APPARATUS.

THE FROG-BOARD MYOGRAPH AND THE MANOMETER TAMBOUR.*

WINFIELD S. HALL, M.D.
Professor of Physiology, Northwestern University Medical School.
CHICAGO.

THE FROG-BOARD MYOGRAPH.

The term myograph was originally applied to the whole apparatus used in recording the contraction of a muscle. The pendulum myograph of Helmholtz included the muscle-clamp, the muscle-lever and the moving surface (pendulum) on which the myogram or muscle-tracing was recorded. After the rotating cylinder came into use as a recording surface under the name of the kymograph, the term myograph has been applied to that portion of the apparatus which represented the muscle-clamp and the lever with the load and the tracing point. Such an apparatus traces on the kymograph the muscle-curve or myogram.

The myograph has taken several forms: In the simple myograph of Helmholtz, in the muscle-signal of Du Bois Reymond, and in several other forms the muscle is exposed to the atmosphere. The changes wrought by the atmosphere soon put the muscle-nerve preparation into an abnormal condition and the responses to stimuli are not typical. In fact, the evaporation of moisture soon condenses the tissue-plasma sufficient to induce a typical "salt-tetanus." The application of normal saline solution can temporarily, but only temporarily, avert such a result.

To reduce to a minimum the effect of atmospheric changes the so-called "moist-chamber" was devised. This consists of a glass chamber which enclosed the muscle and nerve and the electrodes with the muscle clamp. A wire or thread passes through the bottom of the chamber to the tracing lever. The air in the chamber is kept saturated with moisture by a wet paper or sponge within. This device overcomes to a large extent the difficulties with which one must contend in attempting to work with the exposed muscle. There is one serious difficulty, however, which has not been mentioned and which is not corrected by the moist-chamber myograph, namely, the cutting off of the muscle from the blood and lymph circulation. In the classic method of making a muscle-nerve preparation from the gastrocnemius muscle and sciatic nerve of the frog, the muscle and nerve, with a portion of the femur, are completely removed from the frog's body, thus not only exposing them to atmospheric changes, but removing them completely from connection with the circulatory system.

For fundamental experiments on the elementary tissues, and for work with drugs in pharmacology, it is of very great importance to have a myograph that is simple and inexpensive and which does not involve disturbing the circulatory system. The importance of the last point can not be over-estimated. The circulatory system not only brings a continuous supply of nutriment and oxygen to the muscle, but carries from the muscle the accumulating products of fatigue and thus enables the muscle to do much more work than would otherwise be possible.

In pharmacologic experiments it enables the experimenter to watch the influence of drugs carried to the muscle in the normal way, rather than applied in some artificial and abnormal way.

The frog-board myograph is a new form of myograph so constructed as to permit all experiments usually performed on the gastrocnemius-sciatic preparation without exposing the active tissues to the atmosphere or disturbing the blood supply. The instrument is constructed as follows: An oaken base about one-fourth of an inch in thickness supports a cork plate of equal thickness; the cork plate presents a surface about 10 by 25 centimeters. (Fig. 1.) The lever holder at the end of the plate is constructed of thin sheet steel and slips from side to side in order to bring it opposite either leg of the frog.

The distance from the axis of the elbow-lever to the thread-eye is the same as that to the weight, therefore,

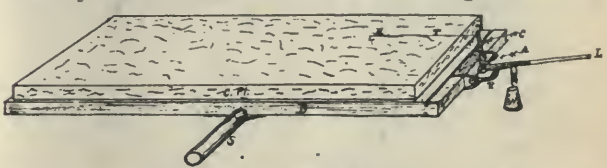

FIG. 1.—FROG-BOARD MYOGRAPH.

S, the shaft which is clamped to the upright stand; B, the oaken base; C. Pl, the cork plate to which the frog is fixed; A, the lever axis and slide lever-holder; W, the weight; L, the light lever about 20 cm. in length; H, the tendon hook which is joined through the thread T, which passed through the eye and under spring catch (c); R, the lever rest.

the weight lifted by the muscle is the actual weight hung upon the weight link. When the lever passes a little below the horizontal position it comes into contact with the rest. This rest can be used in "after-loading" a muscle. For further description of the instrument, see the figure and its description.

In the use of the frog-board myograph one proceeds as follows: The frog is pithed and pinned, dorsum up, on the cork-plate, with the feet at the lever end. The tendo-achillis is exposed and loosened from the tarsal ligaments, the tendon-hook (H) is passed through the tendon and the length of the thread adjusted at (c). The skin on the thigh is opened to the extent of two centimeters and the biceps femoris muscle removed, the sciatic nerve carefully separated from the sciatic artery and placed on the insulated electrodes. Stimulation may be made from time to time for a period of several hours before the preparation becomes exhausted.

SUMMARY.

1. The frog-board myograph is a convenient and inexpensive myograph especially adapted for work in general physiology and in pharmacology.

2. Its advantages over other similar instruments are as follows:

I. The muscle-nerve preparation can be made in at most one-fourth the time required for the classic preparation.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee.

II. The muscle and nerve are not exposed to atmospheric changes.

III. The circulation of the tissues is not disturbed. This has the advantage (1) of permitting the study of the action of drugs on muscle-tissue under normal conditions, (2) of studying fatigue without the accumulation of fatigue products under abnormal conditions.

THE MANOMETER TAMBOUR.

The second piece of apparatus to which I propose to call your attention is the manometer tambour (Fig. 2).

A very large number of research problems require the recording of blood pressure of the animal—rabbit or dog—under observation. In the physiologic or in pharmacologic laboratories where such observations are in progress almost daily, it is not difficult to get very satisfactory results with the classic apparatus, which consists of a mercury manometer whose proximal tube (p) is joined through the medium of pressure tubing (p t) to the canula (c), the pressure tubing being interposed at (T) by a T-tube, one limb of which passes to the reservoir containing a one-half saturated solution of $MgSO_4$ or some other agent for retarding coagulation. Into the distal limb of the manometer (d) there is fitted, in the classic apparatus, a float which rests on the mercury, following more or less accurately the variations in the level and carrying a vertical rod which slides through a guide in the upper end of the distal limb and bears at its upper extremity a horizontal reed, bearing at one end a tracing point.

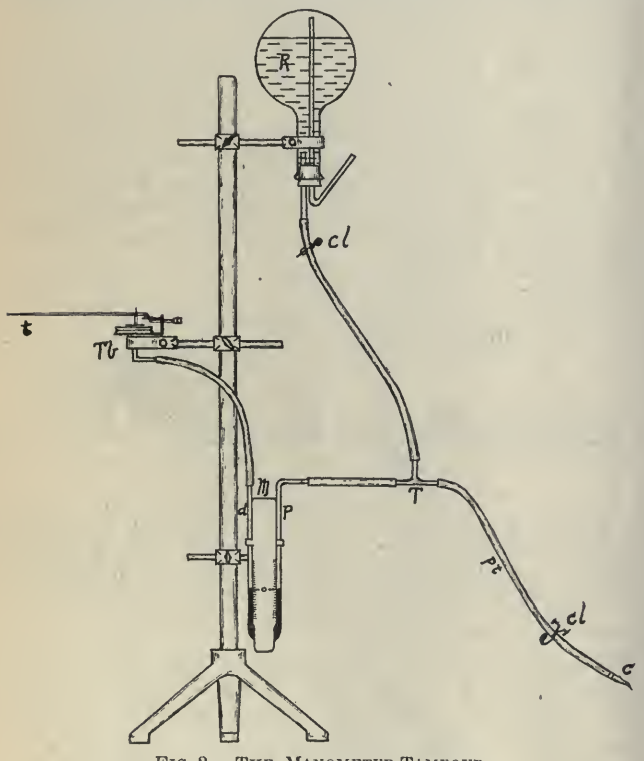

FIG 2.—THE MANOMETER-TAMBOUR.

M, manometer; Tb, tambour; R, reservoir filled with ½ sat. sol. $MgSO_4$; T, T-tube; Pt, pressure tube; Cl, clamp; C, canula; P, proximal limb of manometer; D, distal limb of manometer; T, tracing point of tambour lever.

There are two serious difficulties with this float. First, it is likely to fail to work properly just at the time when you are most anxious that there should be no hitch in your observation, though if the apparatus is in almost daily use this difficulty is not a serious one. The serious objection against the float is, that it does not follow accurately the movement of the mercury. The mercury starts up a little before the float does, and the float itself has so much inertia that the actual movements of the mercury are not shown at all by it. In order to overcome this difficulty, and to be able to record accurately the movements of the mercury meniscus, the following variation of the classic apparatus was contrived.

A small tambour was joined to the distal end of the manometer by a piece of pressure tubing and supplied with a very delicate tracing lever which magnifies the movements of the membrane 10 or 20 times, as desired, the levers being variable in the construction of the instrument. The surface of the tambour should not be larger than 15 mm. in diameter. The diameter of the mercury meniscus should probably be not less than 3 mm. in diameter. With this ration between the two surfaces and the levers multiplying 10 to 20 times, the most beautiful arterial pressure tracing can be obtained, showing not only the respiratory and percussion waves, but also the dicrotic wave clearly superimposed on each cardiac wave.

This apparatus, as above described, has one limitation which may, for certain kinds of work, seem to be a disadvantage. The pressure tubing leading from the distal end of the manometer to the tambour (Tb) is not attached to the manometer until after the rise of the mercury in the distal tube following the removal of the clamp (cl). After the tambour is attached to the manometer every movement of the mercury is shown by corresponding movements of the tracing point (t). Should there be a sudden rise or sudden fall of pressure, it will be instantly and clearly shown by corresponding rise or fall of the tracing. Should there, however, be a very gradual rise or a very gradual fall, owing to physiologic changes in the tonus of the blood vessels, for example, or perhaps by the gradual action of some drug on the animal under observation, this will not be shown by corresponding rise and fall of the tracing. It will, however, be shown by the stand of mercury in the distal limb of the manometer, and this may be easily read off or noted from time to time.

To offset this slight disadvantage, one has the two advantages above mentioned, namely, accuracy of the tracing of all the quicker movements of the mercury and the assurance that one's apparatus will always work.

PATHOLOGY AND CLINICAL HISTORY OF AMEBIC DYSENTERY.*

H. F. HARRIS, M.D.
ATLANTA, GA.

PATHOLOGY.

The alterations found in the bodies of those dead of amebic dysentery vary greatly, depending on the time that the disease has existed, the extent of the intestinal lesions, and the complications that have arisen during the course of the malady—some lesions being always found, while others are encountered with greater or less frequency. Among the most common of these is emaciation, which, especially in chronic cases, is often extreme. On opening the abdominal cavity peritonitis is occasionally encountered, which may be very mild, and frequently extends but little beyond that portion of the membrane that surrounds the large gut, but in those

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

cases where perforation has occurred a general suppuration of the entire cavity is found, except it be that adhesions of such a character have previously formed that the contents of the intestine are poured into a closed sac cut off from the general peritoneum; under such circumstances the condition is practically one of abscess formation. Though not invariably the case, the large gut is usually adherent to the coils of the small intestine or other viscera, and it is sometimes united to the walls of the abdomen by newly-formed bands of fibrous tissue; in some cases neighboring portions of the large intestine are united to each other. As a result of these adhesions the colon is often drawn from its normal position, and in some cases is greatly distorted. It is generally found that the walls of the gut are so thinned in places that it is only with the greatest care that it can be removed without being torn. On opening the intestine it is found that its coats are much thickened in some situations, and that on its surface there are numerous ulcers. The extent of the ulceration varies greatly in different cases, it being sometimes slight and confined to one portion of the gut, while in other instances the entire mucous surface of the viscus is denuded; it is, however, fortunately true that in fully half of the cases the lesions do not extend upward beyond the beginning of the transverse colon. The ulcers vary in size from those that are microscopic to others that cover a large portion of the mucous surface of the gut; as a rule, however, they are separated from each other by more or less normal mucous membrane. The edges of the ulcers are prominent and project above the general surface. The floors of these lesions are ashen-gray in color, and are almost always covered by a layer of mucus, in which there are particles of undigested food and masses of sloughing tissue; when examined under the microscope this mucus is found also to contain many swollen cells, leucocytes, amebæ and myriads of bacteria. The edges of the ulcers are practically all undermined, and not uncommonly, it is said, fistulous tracts connect them when near each other, though I have never myself been able to demonstrate this. These lesions may be rounded or irregularly shaped, but more commonly they are oblong, and lie transverse to the long axis of the intestine. It is rather curious that these portions of the gut that lie nearest the attachment of the mesocolon are, as a rule, but little affected. The mucosa between the ulcers is usually somewhat reddened, but it may appear entirely normal.

The intestinal lesions of this disease are almost always confined to the large gut, but now and then the process extends up into the small intestine for a short distance. I saw the appendix involved in one case; the small gut was also affected. It is remarkable that in cases where recovery occurs—even in instances where the disease was severe, and had existed for some time—the large intestine after a short time rarely shows macroscopic evidence of the pronounced ulceration that must have existed.

Our knowledge is very meager as to the exact nature of the finer alterations that occur in the intestine in the early stages of amebic dysentery in the human being, but the changes that take place in the large gut of the dog have been studied by several investigators. The sequence of events that occur in the puppy after having received an injection of material containing living amebæ seems to be briefly as follows:

Collections of amebæ occur on the mucous surface of the intestine, and quickly thereafter the epithelial cells on which these organisms lie exhibit catarrhal changes and drop off from their basement membranes; the blood vessels in the tissues below dilate, and the lymphatics become enormously distended with fluids. There is an increase in the number of lymphoid cells, and many of the large phagocytes of Metchnikoff collect in the part; simultaneously some of the dilated blood vessels burst, and we find as a consequence that there are many red and white cells in the affected area. Following this, the basement membrane on which the desquamated epithelial cells originally lay breaks down and disappears, and the blood that was free in the tissues at once finds its way to the surface and becomes mixed with the mucus and other materials present within the lumen of the gut. Necrotic changes in the tissue surrounding the crypts quickly follow, and these structures fall out, leaving ulcers that extend down to the muscularis mucosæ. The coat just named offers considerable resistance to the downward progress of the ulceration, but it eventually gives way, and the process passes into the submucosa. The tissues composing this coat in their turn undergo necrotic changes, which extend rapidly down to the circular muscular layer, and laterally in every direction. The walls of these ulcers are not made up of the pre-existing tissues of the part, but are composed of enormous collections of phagocytes of Metchnikoff, and red blood cells, with a smaller number of polymorphonuclear leucocytes and lymphoid cells, and a few plasma cells.

This brings us to the conditions practically always found in the human being dead of amebic dysentery. When we examine the intestine microscopically it is found that all of the characteristic lesions extend into the submucosa, though in rare instances superficial ulcers do occur, which, however, appear not to have any connection with the predominant process, and will therefore not be considered. The mucosa that lies at a short distance from the true ulcers, as a rule, shows astonishingly little change, but as the edges of the lesions are approached the cells lining the crypts often exhibit decided catarrhal change, and the blood vessels in the surrounding tissues are frequently considerably dilated. Amebæ are but seldom found either within the lumina of the glands or in the tissues that lie between them. At the edges of the ulcers the mucous coat generally terminates abruptly, but now and then this layer extends outward over the surface of the ulcer to a greater or less distance; this outgrowth of mucous tissue is composed mainly of deformed and only partially developed crypts that do not become attached to the underlying tissues; these bands are sometimes reflected back over the normal mucosa. In rare instances the process of healing over of the ulcers may be observed; this consists in the epithelial cells growing downward from the edges over the surfaces of the ulcers, and ultimately covering them with a single layer of cells, no new crypts being formed. The floors of the open ulcers are usually formed by one or the other of the muscular coats—generally the inner—though the necrotic process not uncommonly extends completely through these layers, and we find only the thickened peritoneum interposing between the abdominal cavity and the lumen of the intestine. Irrespective of the depth to which the ulceration has extended the surfaces of the lesions are always made up of partially necrotic tissue, in which there are multitudes of bacteria, many amebæ, and great numbers of cells. In these situations swollen bands of fibrous tissue that appear hyaline and take acid stains intensely are frequently

found; they contain no recognizable nuclei. It is noteworthy that the elastic tissue fibrils are quite as well, if not better, preserved in these areas than the fibrous structures; this is exactly opposite to what occurs in the dog under similar circumstances, and may account for the great rapidity with which the tissues in these animals break down. Just beneath the surfaces of the ulcers the pre-existing tissues of the parts are found in varying stages of necrosis depending on the depth, and these structures are separated by accumulations of fluids between them and the presence of a vast number of cells; these consist of polymorphonuclear leucocytes, lymphocytes, plasma cells, connective tissue cells, mast cells and red-blood corpuscles. Amebæ are commonly present in these areas. The blood vessels are for the most part dilated and filled with blood; in many instances the vessels contain thrombi. The vessel walls are frequently necrotic, particularly on the side nearest the ulcers; amebæ are often found within their lumina. The lymph spaces and lymph channels are universally distended with fluids and cells. The epithelial cells that formally lined these vessels become greatly swollen, and almost without exception desquamate, and then lie loosely within the lumina of the vessel; mixed with these cells red blood corpuscles, leucocytes and amebæ are frequently found. Lower down in the walls of the gut these alterations become less pronounced, but the proximity of the pathologic process is usually evidenced by the presence here and there of small collections of lymphocytes, and great numbers of mast cells are scattered throughout the tissues. Newly formed masses of fibrous tissue are not uncommonly found at a considerable distance from the point of ulceration. Where the necrotic changes have passed through the muscular layers the subperitoneal coat is always greatly thickened, and the tissues composing it exhibit changes similar to those that have been described as occurring in the more superficial portions of the intestinal wall. While it is true that the amebæ, as a rule, are rather behind than in advance of the areas of greatest pathologic change, they are not uncommonly encountered at considerable distances from the edges of the ulcers. Under these circumstances I have been struck with the fact that they are usually acidophilic, and that their nuclei are not colored by basic dyes. Furthermore, numerous bacteria that stain well are found within them, and in many instances the parasites are undergoing disintegration, and the micro-organisms that they contain are being disseminated into the surrounding tissues. The changes that occur in the tissues at the lateral margins of the lesions resemble, on the whole, those that take place at their bases, with the exception only that the structures composing the submucosa are much more susceptible to the action of the poison of this disease than are those that make up the remaining coats of the intestine; this is strikingly shown by the resistance of the muscularis mucosa, which always projects out over the necrotic submucosa, and supports the overlying mucous coat. It is thus seen that the undermined edges of the ulcers in this, as in other intestinal diseases, are due to the power of the muscular coats to resist the poisons that produce the pathologic change. Fibrin is frequently present in the tissues of the submucosa in the neighborhood of the necrotic areas. In the lateral margins of the ulcers amebæ are numerously present, more so than in any other part of the intestinal walls; they lie in the necrotic structures, and somewhat within the tissues that are more or less normal, but do not penetrate very far as a rule. The changes in the tissues are always in advance of the great body of amebæ, this again clearly showing that if they be in reality the cause of the pathologic process they must necessarily act by producing some poison that is absorbed into the tissues. It is noteworthy that the lymph nodes that are present in the mucosa and submucosa show no marked increase in size, and exhibit, as a rule, but little alteration until the diseased process actually includes them, when they become necrotic and break down just as do the other structures.

Following acute amebic dysentery—and strangely enough appearing to develop only during the first few weeks of the disease—abscess of the liver may occur. These lesions may be situated in any part of the liver, and I do not think from a study of the literature that they are so strictly solitary as they are generally supposed to be, but miliary abscesses, such as occur in pyemia, very rarely take place. Any part of the liver may be involved, but the convex surface of the right lobe is most commonly affected. These abscesses, if not interfered with surgically, may rupture into the intestine or neighboring cavities, and may even open externally; there seems, however, to be a marked predisposition on their part to penetrate through the diaphragm and ultimately break into the lung. When this occurs an abscess of the lung develops, the contents of which eventually discharge through the bronchi. The contents of the liver abscess is made up of rather dark, pus-like material which on microscopic examination is found to consist of a very few cells, a great amount of granular debris, and numerous amebæ. Amebæ are always found in these abscesses—this being even the case in dogs where these lesions follow experimental dysentery. The walls of the liver abscesses may consist merely of disintegrating liver substance, or may be made up where the lesion has existed for some time, of a thick mass of fibrous tissue containing numerous lymphoid and plasma cells. It is noteworthy that the amebæ never penetrate into the walls of the liver abscesses, but are very frequently found just along the edges. The liver cells in the vicinity of the lesions show a very peculiar degenerative change which consists in the formation of nucleated bodies that bear considerable resemblance to amebæ. Bacteria are usually found in and around the walls of these abscesses. The blood vessels in the area surrounding the lesions usually contain no blood, but are filled with a granular detritus. In some instances areas of rhexis occur around the edges of the abscess.

It appears to me that there can be little doubt that the amebæ reach the liver by means of the portal circulation, though it has been assumed by some that the organisms get into the general peritoneal cavity, find their way to the liver, and burrow into its substance. The fact that amebæ are very frequently found within the blood vessels of the intestinal wall, even when no thrombosis exists, would seem to make it necessary that they would inevitably reach the liver substance.

SYMPTOMATOLOGY.

Amebic dysentery is a disease that frequently sets in acutely, but almost, if not quite, as commonly the beginning is gradual. In the former class of cases there is nothing in the symptoms at first that distinguishes the disease from the ordinary acute dysentery, which is so extremely common in the southern part of the United States in the spring and summer. In these instances the disease begins with diarrhea, quickly followed by stools of a dysenteric character; the patient complains of pain and tenesmus in the abdominal region,

and there is at the same time a decided quickening of the pulse and some fever. In the course of a few days or weeks the severity of the symptoms usually somewhat subsides, but in exceptional instances the patient slowly grows worse, and death occurs in from two to three weeks. In those cases where improvement follows the acute onset the disease seems always to become chronic, and it is in this stage that the patient usually consults the physician. Where the disease begins gradually the sufferer is rarely able to state with definiteness the time when his trouble began; he remembers only that about a certain time he began to note that his bowels would be loose for a day or so, this being followed by constipation. There were a number of such periods of alternating constipation and looseness of the bowels, but it was observed that the period between the diarrheal attacks became less and less, until finally a condition was reached where there was several movements of the bowels in twenty-four hours. About this time the patient usually begins to observe that the stools contain some blood, and he has slight attacks of pain and tenesmus at the time that the bowels act. At the end of a few weeks the symptoms in every way resemble those that are encountered at an equal period of time from the onset in those instances where the disease began acutely. It is in this stage, after the malady becomes chronic, that it generally comes to the notice of the clinician, as in the class of persons who suffer from this affection a physician is very rarely called in merely for an acute attack of bowel trouble. After the disease becomes chronic it runs an extremely irregular course, sometimes getting well without any apparent cause in a comparatively short period of time, while in other instances it exists for many years. Some time ago Dr. Reginald Fitz of Boston wrote me that he had under his care a patient who had suffered with this malady since the Civil War, and I have myself seen many instances where the disease continued four, six and even eight years. Though somewhat arbitrary, for convenience sake, the affection may be clinically divided into several types, it being understood, however, that either of these may pass into the other at any time, and without any apparent cause:

1. *The Very Mild Form.*—The general health remains fairly good, there is no fever or acceleration of the pulse worthy of mention, and the appetite is good. The number of stools vary from two to six in twenty-four hours. This is the form almost always seen in children.

2. *The Moderately Severe Form.*—In this type of the disease the general health is never good, the appetite is, as a rule, poor, and there is considerable loss of flesh. The pulse is increased in frequency and the temperature goes up toward evening. The number of stools vary from six to twenty in twenty-four hours.

3. *The Very Severe Form.*—In this form of the disease there is great emaciation and loss of appetite, with sometimes nausea and vomiting. The temperature is irregular, but in the afternoon is usually above normal, and the pulse is weak and decidedly accelerated. The extremities are cold, and profuse sweating is quite common. Hiccough is frequent. The stools are watery, and consist very largely of blood and mucus, in which sloughs are sometimes found. The number of stools vary from twenty to fifty in twenty-four hours. It is very remarkable how patients may remain in a condition of this kind for days, and even weeks, and finally recover. It seems to be a peculiarity of all intestinal affections that death may be very closely approached without a fatal termination actually occurring.

There are very remarkable fluctuations in the severity of the symptoms in all forms of the malady, it being not an uncommon observation that the disease passes quickly from the mildest type to the most severe, and vice versa. While we can not always account for an increase in the severity of the clinical course of this affection, it is true that bodily exertion is often followed by a decided exacerbation in the symptoms, and the taking of certain articles of food that disagree with the sufferer frequently occasion distressing results; alcoholics seem to be especially badly borne—the taking of beer being particularly injurious.

Among the symptoms that are occasionally encountered may be mentioned a constant aching in the back that is not relieved by the recumbent posture, a tearing sensation in the region of the colon, great uneasiness in the stomach, and an urgent desire to defecate immediately following the taking of food and edema of the face and feet. In the mild form of the disease the urine is practically normal, but in the severer types albumin is occasionally present. I have examined repeatedly the urine of some of my worst cases for peptone by the method of Hoffmeister, with negative results. In the severer forms of the disease the chlorids are often diminished, and in the worst cases may be totally absent. Their reappearance after having been absent from the urine is a most favorable indication. In the milder forms of the disease the stools may appear almost normal in every way, but a careful inspection will usually reveal the presence of small particles of bloody mucus upon the surfaces of the fecal masses. In the severer types of the malady the movements contain considerable quantities of mucus and blood, and are quite soft in consistency. In the worst forms the fecal discharges consist almost entirely of blood and mucus; stools of this character, occurring in a chronic intestinal affection, I consider entirely characteristic, and even in the absence of a microscope I should feel but little hesitation in making a diagnosis of amebic dysentery. In some cases just before death the quantity of mucus becomes decidedly lessened, the stools consisting of an extremely thin, dark, blood-stained fluid. The feces are, as a rule, alkaline in reaction, but are occasionally slightly acid in mild cases. On microscopic examination the stools are found to consist of partially digested food, much mucus and blood, pus, large epithelioid cells, multitudes of bacteria, and varying numbers of amebæ. Cercomonas are sometimes encountered.

The most important of the complications of amebic dysentery is liver abscess; out of ninety-five cases this has occurred fifteen times—once in a boy. As has been before stated, this complication always arises during the acute period of the disease, there being no instance with which I am acquainted in which it occurred later. It appears to be more common in the northern portions of our country than in the south, as I myself have seen this in only two instances out of fifty-two cases. It is, however, quite likely that the proportion is greater than this, even here, as almost all of my cases were seen after the disease had become chronic. The symptoms of liver abscess are by no means always characteristic, there being many instances recorded where the disease lay latent for a considerable period of time without it being suspected. The usual symptoms are a throbbing or aching pain in the region of the liver, which may be reflected to the right shoulder, chills and fever of an irregular character, and rapidity of the pulse; the appetite fails, the tongue becomes coated, the patient rapidly loses flesh, and jaundice is occasionally encountered. On physical ex-

amination the liver is found to be enlarged; a fullness or marked protuberance sometimes develops at the lower margin of the ribs.

When the liver abscess opens into the lung, as it most frequently does, abscess of this organ develops. The symptoms of this condition are the usual signs of consolidation in the lung, with cough and the expectoration of a reddish-brown fluid, which on examination with the microscope is found to contain amebæ. This complication is rare, it having occurred in only three instances out of ninety-five cases of amebic dysentery.

Perforation of the intestine with peritonitis is an occasional complication of this disease; the symptoms are those that are usually observed in cases of this kind. It has appeared to me that the inflammatory phenomena are not so marked as in the septic peritonitis that follows operations.

Appendicitis has been observed in one case. The symptoms would naturally be those commonly observed where this organ becomes diseased, but in the instance to which I refer the clinical course was so mild that the true condition of affairs was not suspected during life.

A STUDY OF THE CASES OF AMEBIC DYSENTERY OCCURRING AT THE JOHNS HOPKINS HOSPITAL.*

THOMAS B. FUTCHER, M.B. (TOR.)
Associate Professor of Medicine, The Johns Hopkins University.
BALTIMORE.
(From Professor Osler's Clinic, The Johns Hopkins Hospital.)

It is not the intention in this paper to attempt a complete historic account of amebic dysentery. I wish merely to recall the fact that it was Lösch,[1] of St. Petersburg, who in 1875 was the first to give an accurate description of amebæ in the stools of a dysenteric patient. Although Lambl and Cunningham had previously described amebæ in the stools of infants and cholera patients, it remained for Lösch to associate the amebæ with dysentery in the relation of cause to effect. It was also Lösch who gave to the organism the name *Amœba coli,* a name that is still in very general use. Kruse and Pasquale advocate the adoption of the term *Amœba dysenteriæ,* first suggested by Councilman and Lafleur, to designate the pathogenic ameba, reserving the name *Amœba coli* (Lösch) for the non-pathogenic ameba occasionally found in the normal healthy intestine. In America, amebæ were first found by Dr. Osler,[2] who observed them in 1890 in the pus of a liver abscess originating in Panama and operated on by Dr. Tiffany, of Baltimore. I purpose attempting to give as concise an account of the disease as possible, basing the description largely on our observation of the disease and its complications as seen at the Johns Hopkins Hospital.

RELATIVE FREQUENCY.

From May 15, 1889, the date of the opening of the Johns Hopkins Hospital, to May 1, 1903, or for a period of nearly fourteen years, there have been in all departments 120 cases of amebic infection. This was out of a total of 42,614 admissions to the institution. Of the 120 cases, 118 had been admitted to the medical wards. The total number of medical patients during this period was 15,817, so that the medical amebic cases constituted 0.74 per cent. of the total medical admissions. Of the two remaining cases, which were admitted to Prof. Halsted's surgical wards without having been medical cases before or after, one had an amebic abscess of the liver and the other an amebic abscess of the floor of the mouth. It may be safely said that these 120 cases represent pretty accurately practically all the cases of amebic infection that have been admitted to the hospital. It is doubtful whether very many have escaped observation. Since Dr. Osler's first observation, in 1890, and the appearance of Councilman and Lafleur's[3] classical monograph on the subject, in 1891, careful examination of the stools and contents of hepatic abscesses have been made in all suspicious cases. Excluding the case of abscess of the lower jaw containing amebæ, the remaining 119 cases were made up of amebic dysentery or amebic hepatic abscess cases. Only cases in which the histories positively state that amebæ were found are included in the series. Three cases in which a diagnosis of amebic dysentery was made, but in which there is no record in the history of amebæ having been found in the stools, have been omitted. These were in all likelihood actual amebic infections, however, the failure to note the presence of amebæ being an oversight. So also in connection with hepatic abscesses, only those in which there is a definite statement that amebæ were found in the contents of the abscess or in sections of the abscess wall have been included. Those in which no amebæ were found, but which proved sterile on bacteriologic examination (a fact pointing rather strongly toward an amebic origin), have been omitted.

ETIOLOGY.

After the discovery of *Bacillus dysenteriæ* (Shiga) as a cause of epidemic and sporadic dysentery, there was for some time considerable doubt expressed as to whether the *Amœba dysenteriæ* played such an important rôle in the causation of amebic dysentery. It was thought that possibly the intestinal ulceration was first started by the Shiga bacillus, and that the ameba was a later invader, and played a rather secondary rôle. Those who have had most experience with the dysentery bacillus, including Flexner among others, state that there is unquestionably a form of dysentery which is quite independent of that produced by that organism and actually due to the inroads of the *Amœba dysenteriæ.* We can again, therefore, use the term amebic dysentery with full confidence. The pathogenic agent is unquestionably the *Amœba dysenteriæ.*

This parasite is placed by Leuckart in the class *Rhizopoda* of the *Protozoa.* It is a unicellular organism, varying in size between 8 and 37 microns, according to Braun,[4] but usually between 12 and 26 microns, the average diameter being about 20 microns. Whereas in different cases the amebæ may vary greatly in size, in the same case they are usually of a fairly uniform dimension. The body of the ameba consists of two portions: the inner granular portion is called the endosarc or entoplasm; the outer, clearer, hyaline portion is termed the ectosarc or ectoplasm. The division into these two parts is not clearly made out in the resting stage, but becomes very distinct in the actively motile organisms. The greater part of the body of the cell is comprised of the finely or coarsely granular endosarc. This portion often contains several vacuoles of varying size. A

nucleus can occasionally be made out in the fresh unstained ameba; more distinctly in the stained preparations. It averages about 6 microns in size, and is situated in the endosarc, near its border. A nucleolus can be recognized in the stained specimens. The ameba frequently contains foreign bodies. Red blood cells constitute one of the commonest inclusions. The number of red cells contained may reach as high as fifteen or twenty. Included red cells are apparently more numerout in acute cases. Micrococci, bacilli and granular debris are not infrequently seen within the body of the cell.

Probably the most striking thing about the *Amœba dysenteriæ* is its motility. This may present itself in two forms, either a change in shape or a change in place. The change in form is also of two kinds. A pseudopodium, consisting of a process from the hyaline ectosarc, may be seen to be protruded, and in a few minutes attracted into the body of the cell again. A more remarkable change in form is occasionally observed. This consists in the sudden throwing out of a process of the ectosarc, which instantaneously partially or completely encircles and envelopes the cell. The movements of locomotion are most interesting to watch. They seem almost purposive in their character. A hyaline process is thrown out from one border of the parasite, and the granular endosarc, with its inclusions, rapidly flows into the process. By the continual throwing out of a process from the same side of the cell an ameba in a very few seconds will cross the field of the microscope. In some of these very actively motile parasites it is almost impossible to differentiate ectosarc and endosarc, the ameba changing its place by a rapid rolling or flowing motion. In a general way, it may be stated that the more acute the course the more rapid seem to be the movements of the amebæ. When a satisfactory portion of mucus has been obtained, almost the entire field with the oil immersion lens may be seen to be comprised of very actively motile organisms. Cold tends to retard the activity of the parasites, although they will remain fairly active, often for hours, at the room temperature. When the temperature falls below 75 F. the ameboid movements cease, but they may be again started by gently raising the heat to the body temperature by carefully warming the slide over a spirit lamp. With a warm stage, the amebæ will retain their motility almost indefinitely. The activity of the ameba is immediately arrested by a solution of quinin of the strength of 1 to 5000. During the process of death of the organism vacuolization of the cell occurs.

It is not known definitely how the ameba reproduces itself. By analogy, however, one is lead to assume that this takes place by fission or sporulation. The ameba is stained by various basic anilin dyes. The staining methods, which will not be given here, are not perfectly satisfactory, although there is no difficulty in recognizing the organism in stained sections of an intestinal ulcer or wall of an hepatic abscess. Mallory and Wright[5] advocate thionin as a differential stain. Their method aids very materially in differentiating amebæ in sections from mastzellen, with which they are liable to be mistaken. With their thionin stain the nuclei of the amebæ and the granules of the mastzellen are stained brownish-red; the nuclei of the mastzellen and of all other cells are stained blue.

Resistant forms of amebæ, similar to the gamete forms of the malarial parasite, have been noted by Cunningham, Grassi and Calandruccio, and by Quincke. These "encysted amebæ" are believed by these observers to be necessary, under certain conditions, for the transmission of the disease from one person to another.

The ameba is very difficult to cultivate. Kartulis used straw-infusion, and claimed to have been able to grow the parasite. Objections were later made to his technic, as it was believed that his positive results may have been due to accidental contamination. Celli and Fiocca[6] succeeded in obtaining pure cultures of the ameba. They describe two phases in the life cycle—the ameba form and the cyst form—and they state that the amebæ multiply by division.

(*a*) TYPES OF AMEBA FOUND IN THE STOOLS.

It is now well recognized that amebæ may occur in the stools of healthy persons or in the discharges of patients suffering from other diseases, without their having in these cases any pathogenic action. Thus they have been found in cases of chronic diarrhea, intestinal tuberculosis, typhoid fever, hemorrhoids, and other affections.

As a result of careful study of the amebæ found in the feces, supported by inoculation experiments, Quincke and Roos[7] have been led to the conclusion that there are three different varieties of amebæ in the stools of human individuals. The names which they give these different varieties, with their pathogenic actions, are as follows:

1. *Amœba intestini vulgaris,* 40 microns in diameter, coarsely granular, and not pathogenic to either human beings or cats.

2. *Amœba coli mitis,* the same size, pathogenic for man, but not for cats.

3. *Amœba coli* (Lösch) or *Amœba coli felis,* up to 25 microns in diameter; pathogenic for both man and cats, and producing dysentery in both.

It will be seen that the second variety, the *Amœba coli mitis,* which is pathogenic for man only, is much larger than the third variety, the ordinary *Amœba coli* (Lösch).

In our series of 119 cases of dysentery we have no positive evidence that we were dealing with any other than the usual *Amœba dysenteriæ.* In one or two cases, owing to the average diameter of the parasite found being rather smaller than that of the ordinary ameba, it was thought that we might be dealing with a special type of the parasite.

(*b*) DISTRIBUTION OF THE AMEBÆ IN THE HUMAN BODY.

The usual habitat for the *Amœba dysenteriæ* is in the large intestine. Where complications follow, it may be found in other situations. Thus it occurs in the contents of liver abscesses, in the sputum of patients with hepato-pulmonary abscess, and in the pleural and peritoneal cavities when a liver or pulmonary abscess breaks into one or other of these. Other situations in which amebæ have been found are as follows:

1. In the buccal cavity—the so-called *Amœba gingivalis* of Gros and *Amœba buccalis* of Sternberg. These forms were found in the tartar scraped from the teeth, and are regarded as being identical with the *Amœba dysenteriæ.*

2. In the urogenital tract. In 1889, Baelz described, under the name of *Amœba urogenitalis,* large, actively motile amebæ in the urine and vagina of a young woman, 23 years of age, who died of pulmonary tuberculosis. Other similar observations were reported.

5. Mallory and Wright: Pathological Technique, p. 293.

6. Celli and Fiocca: Centralblatt f. Bakteriologie, vol. xv.

7. Quincke and Roos: Berl. klin. Wochenschrift, Bd. xxx, 1893, p. 1089.

3. In pieces of necrotic bone. Kartulis observed amebæ in the pus from an area of necrosed bone involving the lower jaw of an Arab, aged 48.

4. In an abscess in the floor of the mouth. This observation was reported by Flexner.[8] The case occurred in Dr. Halsted's wards in the Johns Hopkins Hospital, and, as already stated, is the only one in this series of 120 cases that was not an amebic dysentery or amebic hepatic abscess case. The patient was a male, white, aged 62 years. The amebæ were obtained from the contents of the abscess at operation. Flexner believed that this form of the organism was closely allied to, if not identical with, the *Amœba dysenteriæ*.

(c) SOURCE OF THE AMEBÆ AND MODE OF INFECTION.

Very little is known regarding the source of the ameba and the mode of infection. We are still absolutely unfamiliar with the life history of the parasite outside the body. Inoculation experiments by way of the mouth, with the possible exception of those of Quincke and Roos, with the so-called encysted forms, have been entirely negative. It is highly probable that infection takes place by way of the gastro-intestinal tract, and that amebic dysentery is contracted in much the same way that typhoid fever is.

GENERAL ETIOLOGIC FACTORS.

(*a*) *Geographical Source of Infection in the Johns Hopkins Series.*—The term "tropical dysentery," for many years used almost synonymously for "amebic dysentery," has long been recognized as a misnomer. Amebic dysentery is not confined to the tropics, but often originates in the subtropical, even in the higher temperate zones. Sporadic cases occur in New England, and it will be remembered that last year Dr. Dock[9] reported before this Section a case which originated in Michigan. As the analysis of our cases shows, the disease occurs very frequently in Maryland and the bordering states. Of the 119 cases of amebic dysentery, the disease was apparently contracted in Baltimore in 83, and in the state of Maryland, outside of Baltimore, in 13 cases, or a total of 95 cases contracted within the state of Maryland; 2 in the District of Columbia; 8 in Virginia; 1 in West Virginia; 1 in North Carolina; 1 in Tennessee; 1 in Georgia; 1 in Alabama; 2 in Florida; 1 in Cuba; 1 in Brazil; 4 of doubtful source, the patients being sailors or travelers, and it being impossible to determine where the dysentery was contracted. It will thus be seen that the disease is very frequently contracted in latitudes as far north as Baltimore.

(*b*) *Age.*—The incidence of the disease in the various decades is shown by the following figures: There were 11 cases in the first decade; 8 in the second; 35 in the third; 29 in the fourth; 20 in the fifth; 11 in the sixth; 4 in the seventh; 1 in the eighth. It will be seen that the largest number of cases occurred in the third decade, 35 cases occurring between the ages of 21 and 30. The youngest patient was a male child 2 years 8 months old, and the oldest was a man 71 years of age. The analysis of the series regarding the question of age is of interest in showing the rather frequent occurrence of amebic dysentery in very young children. As stated, there were 11 cases, or 9.4 per cent. of the total, in the first decade, 6 occurring between the ages of 1 and 5, and 5 between 6 and 10 years. It should teach us to keep in mind the possibility that a chronic dysentery or diarrhea in young children may be of amebic origin. This fact was emphasized by Amberg[10] in a paper in which he reported five of the cases of amebic dysentery in children from Dr. Osler's wards.

(*c*) *Sex.*—There is much disparity in the relative prevalence of the disease in the two sexes, as illustrated by this series. There were 108 males and 11 females. It is possible that the out-door life of men render them more liable to infection, by drinking water containing amebæ or by conveying the parasite to their mouths on dirty hands.

(*d*) *Race.*—The series was composed of 107 white and 12 colored patients. Considering the fact that the proportion of whites to blacks in the hospital is about in the ratio of 7 to 1, it would appear that whites are a trifle more frequently attacked, as the proportion of whites to blacks affected was approximately 9 to 1.

(*e*) *Occupation.*—There was nothing in the consideration of the occupation of the patients to throw any special light on the source of infection.

CLINICAL TYPES.

Three groups of amebic dysentery may be made according to the severity of the intestinal symptoms. The cases may be classified as follows: 1. Dysentery of moderate intensity. 2. Grave or gangrenous dysentery. 3. Chronic dysentery. Owing to lack of time, and in order to avoid repetition, these three types will not be described separately. Moreover, the classification is a more or less arbitrary one, and cases may conform to one or other type at different periods. Thus a case of dysentery of moderate intensity may, and often does, become chronic, while a chronic case may take on acute manifestations and assume a gangrenous type.

SYMPTOMATOLOGY.

In many cases the onset is abrupt; in others it is more gradual. It is most acute in its onset in the gangrenous type, which is seen less frequently in the latitude of Baltimore than in the tropics. In the majority of cases the patient is rather suddenly seized with an attack of diarrhea. In a few hours, or a day or two, the dejections assume a dysenteric character, blood and mucus constituting the bulk of the movement. In the severest cases there may be as many as twenty or thirty such movements in the twenty-four hours. In the severe, acute gangrenous cases, large portions of sloughing mucous membrane may be passed. The appetite is impaired, and there may be nausea and vomiting in the initial stages. There is usually fever at the onset, the temperature ranging often betwen 100 and 102 F. When the cases become chronic the temperature may become subnormal. Frequently there is considerable abdominal pain and tenderness in the acute stages. The pain is most marked over the lower part of the abdomen, although it may be generally distributed. It is intermittent and of a colicky character, and usually is worse preceding the movements. In the chronic cases there may be no pain, excepting during the acute exacerbations. Tenesmus may occur, but it is rather the exception. This is explained by the fact that the lesions are usually most marked in the cecum and ascending colon, the rectum in the majority of cases being uninvolved, or only to a slight extent. The tenesmus in bacillary dysentery, on the other hand, occurs much more frequently, and is often very severe, owing to the rectum being usually much more extensively involved.

8. Flexner: Johns Hopkins Hospital Bulletin, vol. iii, 1892, p. 105.

9. Dock: THE JOURNAL of the American Medical Asoociation, 1902.

10. Amberg: Johns Hopkins Hospital Bulletin, vol. xii, December, 1901.

The degree of emaciation in some cases may be extreme, and is only surpassed by that observed in carcinoma of the esophagus. It is rather surprising, however, how little the general health of the hospital cases is affected in many instances, the color and general nutrition being extremely good. The majority of our cases were of moderate intensity, and in these the symptoms soon subsided under proper treatment. In a considerable percentage of cases the disease is subacute from the start, and gradually passes over into the chronic form. These cases are characterized by alternate attacks of diarrhea and constipation. In the periods of exacerbation the symptoms are rarely so severe as in the acute cases, and the diarrhea is usually readily amenable to treatment. These are the cases which are often so difficult to actually cure, and are the ones that so frequently apply for readmission to the hospital. Of our 119 cases, 19 were readmitted one or more times, with a relapse of the dysenteric symptoms. Of these, 12 were readmitted once; 14 twice; 1 three times, and 2 four times. One patient was admitted to the hospital five times in the short period of nine months; another was admitted five times during a period of one year and seven months. During the exacerbation there is pain, frequent passage of mucus and blood, and usually slight elevation of temperature. The patients, as a rule, do not feel very ill. Nutrition remains fairly good, and the marked emaciation usually observed in these chronic cases in the tropics was practically never seen in our hospital series. The numerous evacuations in these cases very frequently give way to constipation in a few days, when the patients are kept in bed and placed on bowel irrigations.

CHARACTER OF THE STOOLS.

As stated, in the earliest days of the attack the movements are very frequent in the severest cases—as many as twenty or thirty movements occurring in the twenty-four hours. These gradually diminish in number until, in fatal cases, there may be only three or four movements daily for the last few days preceding death. This diminution is in large part due to the gradual loss of expulsive power, brought about by the destruction of the muscular coat and the general edema of the bowel.

The earliest stools are small in amount; they consist, after the expulsion of the fecal contents, almost entirely of clear or slightly turbid and very viscid masses of blood-stained mucus, mixed with more or less bright blood. With the progress of the ulceration the stools become more copious, watery, and less homogeneous, and there is less blood. They contain, also, small, opaque or translucent, gelatinous, grayish-yellow masses, varying in size from a pin's head to a split-pea; these are fragments of necrotic tissue from the bases of the ulcers, and they contain amebæ. Where extensive and rapid sloughing occurs, the stools become greenish, grayish, reddish brown, or a mixture of these colors; their consistence is more watery, and they have a penetrating and horribly offensive odor. Not infrequently they contain large sloughs in the form of tough, stringy masses of a grayish or brownish color.

In cases of moderate severity with sudden onset the stools resemble those of the early stages of the grave form. The amount of blood and mucus is liable to be less. In the chronic form the stools are homogeneous, for the most part watery or like thin gruel, excepting during the periods of constipation, and of an earthy, yellowish-brown color. They contain fewer flakes of mucus and seldom any blood or necrotic fragments.

Microscopic Examination of the Bloody Mucus.—In the acute cases, besides the amebæ, whose characteristics have been already described, large numbers of red blood cells, few leucocytes, and a variable number of degenerated intestinal epithelial cells are seen. In a great many of our cases eosinophiles have been present in large numbers. They were found in the stools of all the five children with amebic dysentery reported from Dr. Osler's clinic by Amberg.[10] Charcot-Leyden crystals in rather small numbers are not infrequently present. They usually are most numerous where eosinophiles are present in large numbers. They occurred in four of Amberg's five cases. The stools also contain an innumerable variety of the ordinary intestinal bacteria.

Parasites Other Than the Ameba.—These are not infrequently associated with this organism in the stools. Ciliated infusoria—the *Trichomonas intestinalis* and *Cercomonas intestinalis*—are comparatively frequent associates. When they occur they are usually present in large numbers. One case in this series was of extraordinary interest in that, with the amebæ in the stools, there was also an intestinal infection with the *Strongyloides intestinalis*. This case was reported by Thayer, and is of particular interest in that it was the first case of so-called Cochin-China diarrhea or infection with the *Strongyloides intestinalis* observed in this country. The stools of this patient also contained large numbers of cercomonadids and trichomonadids.

CONDITION OF THE BLOOD.

Anemia of a mild secondary type usually exists, the reduction in the hemoglobin being more marked than that of the red corpuscles. At first thought it would seem natural to expect that with a chronic disease of this kind the red cells would be quite markedly reduced. This, however, was not found to be the case, the red cells, in fact, being nearly normal. In analyzing the blood counts in our records, I have for purposes of comparison kept the cases with amebic abscesses separate from the uncomplicated amebic dysentery cases. In the case of the red counts and the hemoglobin estimations, the averages were made from the first blood reports recorded in the histories after admission. In order to ascertain whether the leucocyte count was of any material value in determining the presence or not of an hepatic abscess, I have selected the highest leucocyte counts in both groups during their entire stay in the hospital. In many of the early cases no blood counts were made, while in the more recent cases in many instances a complete blood count was not made. This accounts for the averages of the red cells, leucocytes and hemoglobin being made from varying numbers of cases.

1. *Cases with Uncomplicated Amebic Dysentery.*—The average of the red cells in 38 cases was 4,802,000 per c.mm.; the average number of leucocytes in 43 cases was 10,600 per c.m.; and the average hemoglobin estimation in 36 cases was 63 per cent. In five cases the red cells were 6,000,000 per c.mm. or over. The comparatively high average of the red cells and the high count in these five cases are probably explained by a concentration of the blood resulting from the frequent bowel movements. It will be further seen that there was a considerable reduction in the hemoglobin and only a very slight leucocytosis. The average blood count then in the group was, red cells, 4,802,000; leucocytes, 10,600, and hemoglobin 63 per cent.

2. *Cases Complicated by Amebic Abscess of the Liver.*—The average number of red cells in 15 cases was 4,250,-

000; the average number of leucocytes in 15 cases was 18,350; and the average hemoglobin estimation in 13 cases was 66 per cent. The average blood count in this group was as follows: red cells, 4,250,000; leucocytes, 18,350, and hemoglobin 66 per cent. It will be seen that the red cells were only 750,000 lower than in the previous group. The leucocytosis was not a high one. The average was 7,750 higher than in the uncomplicated dysentery cases. There were two cases in which the highest count was under 10,000. The highest leucocytosis of all was 53,000.

Some observers hold that there is a great increase in the leucocytes in cases of amebic hepatic abscess and emphasize its importance in the diagnosis of such cases. Few, however, give counts supporting their statements. Although our series shows that the average leucocyte count in the amebic abscess cases is considerably above that in the uncomplicated cases, yet it is doubtful whether the leucocyte count is of any great value as a means of diagnosis. For instance, in the uncomplicated series there were ten cases in which the leucocyte count was above the average in the abscess cases. In two of these the counts were 40,000 and 47,000 respectively.

The average differential count of the leucocytes showed a relative increase in the polymorphonuclears. Considering the rather large number of eosinophiles seen in the stools in certain cases, it was thought that there might be some change in the relative percentage of these cells in the blood. With the object of determining whether there was such a change or not, Dr. McCrae made differential counts in a number of cases, but found the eosinophilic cells present in practically normal percentages.

COMPLICATIONS.

1. *Hepatic Abscess and Hepato-Pulmonary Abscess.*—Abscess of the liver is the most frequent and most serious of the complications of amebic dysentery. Of the 119 cases of amebic dysentery, 27, or 22.6 per cent., developed hepatic abscess. It is impossible to draw an accurate comparison between this percentage and the frequency of this complication in the extensive statistics of British and French physicians dealing with dysentery in India, owing to the lack of mention of the etiologic factor in the latter. In a hospital series, the percentage of hepatic abscess cases would probably be higher than would be the actual percentage outside hospitals, owing to the fact that the severity of the symptoms from this complication would cause the victim to seek admission, whereas the patient with dysentery alone would not be so likely to enter a hospital. There were 24 cases in males and 3 in females. According to decades, the cases occurred as follows: second, none; third, 10; fourth, 5; fifth, 7; sixth, 3, and seventh, 2. It will be seen that the largest number, 10, or 35.7 per cent. of the total cases, occurred between 21 and 30 years. The complication was also most frequent in this decade in Waring's more extensive statistics. Whether there were any special determining factors predisposing the patients to the development of this complication could not be ascertained. In one case direct traumatism in the hepatic region seemed a factor. The Anglo-Indian authorities lay great stress on the predisposing influences, particularly of alcohol, but also of condiments and high temperature.

Relationship to Onset of Dysentery.—The series was analyzed for the purpose of determining the length of time the dysentery had lasted before the symptoms of hepatic abscess manifested themselves. The result was as follows: In 3 cases there was no statement as to how long the dysentery had lasted. In 5, the intestinal manifestations had been so unimportant as to lead the patient to state on inquiry that he had not had diarrhea. Definite data are given in 19 other cases. In eight cases the dysentery had lasted one month or less. In one of these the dysentery and abscess symptoms had come on simultaneously, and in three others the dysentery had lasted only two weeks; in 1 case the dysentery had lasted two months; in 1, three months; in 2, four months; in 1, five months; in 2, six months; in 1, seven months; in 1, eight months; in 1, one year, and in 1, six years. The statement is sometimes made that hepatic abscess only develops in the very acute stages. The above analysis amply proves the contrary. It shows, however, that the largest number did develop within the first month after the onset of the dysentery. It must be emphasized that in one case the intestinal symptoms had lasted one year and in another case the remarkably long period of six years. Probably the most interesting fact of all is that in 5 cases the intestinal disturbance had not been sufficient to attract the patient's attention. In 22 of our 27 cases of hepatic abscess there was clinically or anatomically the existence of amebic dysentery, although in two of these cases there were only the scars of old ulcers. In two of the remaining five cases the intestine seemed normal at autopsy. This is an interesting fact, as it shows that the ulceration may be so slight as to cause no evidence after healing, and yet hepatic abscess may result in such cases. The other three cases were among those that recovered, and no history of dysentery had been obtained, amebæ being present, however.

Number of Abscesses.—The belief, formerly held, that amebic hepatic abscess is nearly always single, is no longer tenable. There may be only one large abscess, but not infrequently there are two or three fairly large abscesses, while, on the other hand, there may be thousands of minute abscesses, some almost indistinguishable to the naked eye. These minute abscesses have also been shown to contain amebæ. In 8 of the cases the abscesses were multiple. The most frequent situation for the single large abscess or for the multiple large abscesses is the upper and posterior part of the right lobe of the liver under the diaphragm. Autopsies were obtained in 22 of the 27 fatal cases of amebic dysentery. Eighteen of these cases were found to have hepatic abscesses. In 10 there was a single large abscess in the upper part of the right lobe.

Spontaneous Rupture of Abscess.—Amebic abscess of the liver may rupture spontaneously. In our series of 27 cases the abscess ruptured into the surrounding viscera or tissues as follows: Through the diaphragm, producing abscesses in the right lung or discharging themselves through the bronchi in 9 cases; into the right pleural cavity, causing an empyema in 3 cases—in one of these a pyo-pneumothorax was recognized clinically; into the duodenum in 1 case; into the inferior vena cava in 3 cases. In one case the abscess extended into the retroperitoneal tissues, involving the muscles of the back and the psoas muscle. In another an abscess in the lower part of the right lobe of the liver invaded the right kidney. This explained a hematuria that the patient had previous to admission. One of the cases was remarkable in that a large abscess in the upper part of the right lobe had entirely healed and had been replaced by a mass of dense fibrous tissue measuring about 3 cm. in diameter. This abscess had previously ruptured through the diaphragm into the lung, and the

patient died from the effects of a large abscess in the lower lobe of the right lung, in which amebæ were found. The opening in the diaphragm was found entirely closed at autopsy. Seven of the abscesses were intact at the time of the autopsy. The series shows, what all statistics have, that the rupture is most frequently through the diaphragm into the lower lobe of the right lung with the establishment of an hepato-pulmonary abscess. The relatively large number of ruptures (three) into the inferior vena cava is of extreme interest. In one case, the inferior vena cava, beginning at a point just above the rupture, contained an organized, decolorized, firm thrombus, which extended upward and projected into the right auricle, which it nearly filled. In addition to the situations above noted where rupture may take place, the abscess may open into the pericardium, the stomach, bladder, colon, or small intestine, peritoneum, or through the skin in the right hypochondrium.

Symptoms of Hepatic Abscess.—The symptoms may be insidious in their onset, or they may be ushered in fairly abruptly. Pain is one of the earliest symptoms. At first it is usually dull and aching, later becoming lancinating and tearing in character. The former is due probably to stretching of the liver, while the latter is attributable to involvement of the peritoneum or pleura. The situation of the pain varies greatly. It may be in the epigastrium, right hypochondriac, lower right axillary, or scapular region. It is quite surprising the large number of our cases that have complained of pain in the region of the right shoulder-joint. This is a reflex pain through the phrenic, which receives large twigs from the fourth cervical. The fever which develops is at first usually of a continuous type; later it becomes remittent, and still later of an intermittent, septic type. At this stage chills are common, and the symptoms may simulate malaria. Profuse sweating is the rule. The pulse ranges between 100 and 140, and there is a certain amount of dyspnea, especially with any pleural or pulmonary involvement. There may be nausea and vomiting. Emaciation may be very marked. The patients have a sallow icteroid tint, and the conjunctivæ have a yellowish hue. The French think that there is something almost pathognomonic in the facial appearance of these cases. Marked jaundice is quite rare. As shown above, there is usually a moderate leucocytosis, the average in our cases being 18,300 per c.mm.

Physical examination may show some fullness in the epigastrium or right hypochondrium. There may be tenderness over the hepatic region, and if the abscess has attained considerable size the edge of the liver will be palpable. If the abscess be situated on the lower aspect of the right lobe or in the left lobe, its presence is more likely to be suspected early then when situated elsewhere. Percussion, when the abscess is of considerable dimensions, will nearly always reveal an increase in the area of hepatic flatness. Owing to the fact that the large abscesses are most frequently situated in the upper and posterior part of the right lobe, it will usually be found that the hepatic flatness will reach much higher than normal in the axillary line, and extending as high as, or higher than, the angle of the scapula. Auscultation may reveal nothing unusual. There may be an audible peritoneal rub over the liver, or, if the inflammatory trouble has extended through the diaphragm, there may be a pleuritic friction rub.

If the extension of the abscess upward be gradual, adhesions may take place betwen the visceral and diaphragmatic pleura, and the abscess may open directly into the lung, with the establishment of a hepato-pulmonary abscess. Rupture of the hepatic abscess into the lower lobe of the right lung took place in 9 of our 27 cases of hepatic abscess, or in 33.3 per cent. The invasion of the lung is usually ushered in by an aggravating cough of a convulsive character. The signs of involvement of the right lung are indicated by an increase in the area of dulness at the right base, feeble, tubular breathing and possible increase in the tactile fremitus. In the cases where the pulmonary abscess communicate with a bronchus, the most characteristic feature is the expectoration of a reddish-brown sputum described by Budd as having an "anchovy-sauce" appearance. The peculiar color of this expectoration is very characteristic. The contents of the hepatic abscess itself are not of this character, and the peculiar color is probably due to the admixture of the hepatic pus with blood as it passes through the lung. Microscopic examination of the expectoration will, on persistent search, practically always reveal the presence of amebæ. They were present in the sputum of all our cases. It further will show abundance of disintegrated pus cells, a few liver cells, some elastic tissue from the lung, hematoidin crystals, and occasionally Charcot-Leyden crystals. If the pulmonary abscess at intervals freely evacuates itself through the bronchus, the physical signs over the affected area may be those characteristic of a pulmonary cavity. The rupture of an hepatic abscess into the lung is usually followed by a decided diminution in the size of the liver as determined by palpation and percussion.

Bacterioscopic and Bacteriologic Examination of Hepatic Abscesses.—In all the cases but one, amebæ were found in the abscess contents. The exception was a case of healed hepatic abscess. Amebæ were found, however, in the pus of a lung abscess, from the effects of which the patient died. The statement that the hepatic abscesses are usually sterile requires to be modified. Not at all infrequently bacteria, in addition to amebæ, are also present. The bacteriologic study of our series of 27 cases gave the following results: The *Staphylococcus aureus* was found in 6; the *Bacillus coli communis* in 5, usually associated with other organisms; the *Streptococcus pyogenes* in 3, and the *Micrococcus lanceolatus* and *Bacillus pyocyaneus* in 1 each.

Avenues of Infection of the Liver.—Two views are held as to how the amebæ reach the liver. One view is that they migrate through the intestinal wall and enter the peritoneal cavity. Once reaching the peritoneum, they are supposed to pass toward the liver, the tissue of which they invade. Councilman and Lafluer considered this the likely mode of infection, and thought it amply explained the occurrence of the large abscesses in the upper part of the liver near the diaphragm, as well as of the multiple smaller superficial abscesses. In support of this view, Lafleur cites a case of dysentery in which a peritonitis existed with amebæ in the exudate over the intestinal coils and over the surface of the liver. Rogers,[11] who has made a study of amebic dysentery and hepatic abscess in India, believes that this is the method of infection in a good many cases.

The most rational theory, and the one that has the largest number of supporters, is that infection of the liver occurs by way of the portal vein. There is ample evidence in favor of this view. Dr. W. G. MacCallum, of the Johns Hopkins Hospital, in a verbal communication, informs me that in a number of recent cases he has found the amebæ in considerable numbers

11. Rogers: British Medical Journal, Sept. 20, 1902.

within the portal capillaries at the margins of the intestinal ulcers. Such a method of infection, it would seem, could alone explain the innumerable small abscesses scattered throughout the entire liver in many of the cases.

2. *Amebic Empyema.*—In two cases the hepatic abscess ruptured directly into the right pleural cavity. In a third case, an amebic abscess of the lung ruptured into the right pleura, giving rise to a pyo-pneumothorax which was recognized clinically.

3. *Perforation of the Colon and Peritonitis.*—Just as in typhoid fever, the intestinal ulceration may become so deep that perforation of the colon eventually results. This occurred in three cases in our series. In one case the patient was operated on within three hours after the perforation occurred. He failed to recover, however.

4. *Intestinal Hemorrhage.*—At first thought it seems somewhat surprising that intestinal hemorrhage is not more frequent, considering the extent of the ulceration in the severest cases. It occurred in 3 cases in the series. Its infrequency is due to the fact that the vessels are thrombosed in the area of infiltration.

Other Associated Infections.—It is of considerable interest that the amebic dysentery was associated with another protozoan infection in a number of instances. Five of the patients also had malaria. Three of these were double tertian and two estivo-autumnal infections. Flexner[12] reported one of these cases and found in addition the *Bacillus coli communis* and the *Micrococcus lanceolatus* in the cultures from various organs. Another case was of extraordinary interest. The patient had suffered from dysentery for six years. On admission it was found that he was also suffering from typhoid fever, confirmed by a positive Widal reaction. The typhoid was complicated by a double thrombosis of the femoral veins. During convalescence he developed an amebic abscess of the liver for which he was operated on, with eventual recovery. One patient had pulmonary tuberculosis.

MORBID ANATOMY.

The intestinal inflammation and ulceration is confined almost exclusively to the large intestine. In 2 of our cases there was slight superficial ulceration in the last few centimeters of the small intestine.

The intestinal lesion consists of ulceration which has been preceded by infiltration of the submucosa due to an edematous condition and to multiplication of the fixed cells of the tissue. In the earliest stage these local infiltrations appear as hemispherical elevations above the general level of the mucosa. The mucous membrane over these soon becomes necrotic and is cast off, exposing the infiltrated submucous tissue as a grayish-yellow gelatinous mass, which at first forms the floor of the ulcer, but is subsequently cast off as a slough. The individual ulcers are round, oval or irregular, with infiltrated undermined edges. The visible aperture is often small compared with the loss of tissue beneath it, the ulcers undermining the mucosa, uniting and forming sinuous tracks bridged over by apparently normal mucous membrane. According to the stage at which the lesions are observed, the floor of the ulcer may be formed by the submucous, the muscular or the serous coat of the intestine. The ulceration may affect the whole or some portion only of the large intestine, particularly the cecum, the hepatic and sigmoid flexures and the rectum. In severe cases the whole of the intestine is much thickened and riddled with ulcers, with only here and there islands of intact mucous membrane. Healing takes place by the gradual formation of fibrous tissue in the floor and at the edges of the ulcers, which may eventually result in partial and irregular strictures of the bowel.

Microscopic Examination.—A notable absence of the products of purulent inflammation appears. In the infiltrated tissues polynuclear leucocytes are seldom found and never constitute purulent collections. Amebæ are found more or less abundantly in the tissues at the base of and around the ulcers, in the lymphatic spaces, and occasionally in the portal capillaries.

Two kinds of lesions occur in the liver. First there are local necroses in the parenchyma, scattered throughout the organ and possibly due to the action of chemical products of the amebæ. The abscesses, as already stated, are either multiple or single. Multiple abscesses are usually small and generally superficial. In an early stage they are grayish-yellow, with sharply defined contours, and contain a spongy necrotic material, with more or less fluid in its interstices. The larger abscesses have ragged necrotic walls, and contain a more or less viscid, greenish-yellow, or reddish-yellow purulent material mixed with blood and shreds of liver tissue. The older abscesses have fibrous walls of a dense almost cartilaginous toughness. A section of the abscess wall shows an inner necrotic zone, a middle zone in which there is a great proliferation of the connective tissue cells and compression and atrophy of the liver cells, and an outer zone of intense hyperemia. There is the same absence of purulent inflammation as in the intestine, except in those cases in which a secondary infection with pyogenic organisms has taken place. The material from the abscess cavity shows chiefly fatty and granular detritus, few cellular elements, and amebæ in variable numbers, which are also found in the abscess walls, chiefly in the inner necrotic zone. Very frequently the pus in the central part of the abscess contains no amebæ. These are found in gradually increasing numbers as the abscess wall is approached. The organisms remain at the margins of living tissue, where they can obtain oxygen, which seems essential for their existence.

DIAGNOSIS.

The diagnosis of amebic dysentery depends on the finding of actively motile amebæ in the stools. In the majority of cases the amebæ will be found in the first specimens examined. When the organisms are few in number, and particularly in the chronic cases during the periods of constipation, many examinations extending over days may be necessary before positive findings are made. It is important that the stool should be examined as soon as possible after being passed and while the feces are still warm. In order to prevent the feces from cooling off it is well to have the patient pass the stool into a warmed receptacle and then to immerse the latter in an outer basin containing warm water. Our routine method in the hospital wards, however, has been to secure perfectly fresh specimens of the intestinal contents by the introduction of the rectal tube. When the stools are fluid considerable quantities of fecal matter may be obtained, and when constipation exists small portions of mucus will be found in the lumen of the rectal tube from which preparations for microscopic examination may be made. In searching for amebæ the portions of the feces to be selected are the particles of blood-stained mucus and the small gelatinous masses consisting of necrotic intestinal mucosa. In examining the specimen microscopically, it is well to use the low

12. Flexner: Johns Hopkins Hospital Bulletin, vol. vii, 1896, p. 171.

power first. In this way the slide can be rapidly looked over and the amebæ will be recognized as larger and more refractile than the intestinal epithelial cells and leucocytes from which they have to be differentiated. Even the ameboid movement can be recognized with this power. When a suspicious looking field has been found the high power should then be used. A positive diagnosis of amebic dysentery should be made only when actively motile organisms have been found. When one finds large, round, non-motile bodies containing one or more red cells one can be reasonably certain that he is dealing with amebæ. A positive diagnosis, however, should be withheld until actively motile organisms are found, which result will almost surely follow in such cases if persistent faithful search be made. There is one type of degenerated epithelial cell which may give rise to confusion. This is an intestinal epithelial cell in which vacuolic degeneration is taking place. The vacuole gradually increases in size at the expense of the remainder of the cell and might be mistaken for the hyaline ectosarc of an ameba. It occupies usually one side and the nucleus is pushed to the other side of the cell. The absence of any ameboid movement should suffice to prevent misinterpretation of these cells. Swollen degenerated leucocytes should give no trouble. The monads are recognized by their peculiar movement and by their different morphology.

When physical signs pointing to hepatic abscess develop in a case of amebic dysentery one naturally suspects that the abscess is of amebic origin. The question of the differential diagnosis between hepatic abscess, subphrenic abscess and pleurisy with effusion will not be considered here. The positive diagnosis of hepatic abscess will depend on the finding of motile amebæ in the contents of the abscess. In a large number of our cases of hepatic abscess contents were obtained for microscopic and bacteriologic examination by means of a long aspirating needle. While some objection to this procedure might be raised, we had no untoward results in any of our cases. The point of introduction of the needle, which should be 8 to 10 centimeters long, will depend upon the suspected position of the abscess. The procedure may be repeated a number of times if the first puncture is negative. The absence of amebæ in the contents does not prove that the abscess is not of amebic origin, for it is a frequent occurrence in cases operated on not to find amebæ until the abscess evacuates itself and until particles of the abscess wall appear on the dressings. The absence or partial absence of pus cells in the contents of an hepatic abscess is always suggestive of its being amebic in origin, because the ameba is not a great pus producer. The bulk of the contents consists largely of granular debris resulting from broken down liver cells. An amebic origin should always be suspected when the cultures prove negative. Amebic abscesses of the liver are not by any means always sterile, however, as has been already amply shown in this series.

When a patient with an hepatic abscess suddenly begins to expectorate quantities of sputum possessing a reddish-brown "anchovy-sauce" appearance, the establishment of an hepato-pulmonary abscess must be considered. The granular character of the pus on microscopic examination and the finding of liver cells and hematoidin crystals confirms this suspicion. Careful and persistent examinations of the sputum will nearly always reveal the presence of amebæ when the hepato-pulmonary abscess is of amebic origin. Amebæ were found in the sputum in all our nine cases in which this complication occurred.

After the discovery of *Bacillus dysenteriæ* some investigators were at first inclined to believe that this organism was the primary agent in setting up the intestinal inflammation and that the *Amœba dysenteriæ* was a secondary invader and of minor pathologic importance. These observers now credit the ameba with full powers to produce the lesions which are characteristic of amebic dysentery. The blood serum of nearly all the cases of amebic dysentery admitted to the Johns Hopkins Hospital during the last two years has been tested in order to ascertain whether it possessed any agglutinative action with the *Bacillus dysenteriæ* obtained from various sources. The test was invariably negative, thus tending to show that *Bacillus dysenteriæ* played no part in the production of the disease in our cases.

COURSE AND PROGNOSIS.

Any one seeing numerous cases of amebic dysentery learns to be guarded in his statements to the patient concerning the ultimate outcome of the disease. Tendency to a relapse of the dysenteric symptoms is one of the striking characteristics of the affection. In the majority of cases the dysentery yields fairly readily to absolute rest and intestinal medication in a very few days, and the bowels may become constipated and move only when the medicated irrigations are administered. The recurrence of the symptoms in patients discharged from the hospital apparently cured, is no doubt due to the failure of the intestinal irrigations to reach the living amebæ buried deep in the cells of the submucosa of the intestines. These organisms that survive eventually multiply in sufficient numbers to again set up the local intestinal ulceration with a consequent relapse of the symptoms.

That the disease is a grave one is amply illustrated by the mortality in the Johns Hopkins Hospital series. Of the 119 cases, 28 or 23.5 per cent. terminated fatally. Hepatic abscess is a very serious complication. Of the 27 cases with this complication 19 died. Five recovered after being operated on. Two of the 9 cases of hepato-pulmonary abscess left the hospital very much improved with good prospects of recovery, although their ultimate fate is not known. One case of abscess refused to remain in the hospital and was not treated. The seriousness of the hepatic abscess as a complication is further emphasized by the fact that the 5 recoveries after operation were out of a total of 17 cases operated on.

TREATMENT.

Until we know something definite of the life history of the ameba outside the human body it will be difficult to prescribe any adequate prophylactic line of treatment. Presumably, however, the same precautionary measures against typhoid infection, especially in connection with drinking water, will prove serviceable in this disease.

When the disease has actually established itself, the patient should be put to bed and kept absolutely quiet until the active symptoms have been controlled. The diet should be simple and easily digestible. A long list of medicines, administered by mouth, has been tried without satisfactory results. Even ipecac, formerly so strongly recommended in the tropics for the various forms of dysentery, has fallen largely into disuse. Local treatment gives the best results. Various astringent solutions have been advocated and may be tried. Large high irrigations of a solution of quinin have given the best results and this has been the routine treatment in our wards. The success of the treatment depends largely

on the method of giving the irrigation. It must be remembered that the rectum in the majority of cases is not at all or only slightly involved and that the ulceration is most extensive in the cecal pouch and in the ascending colon. One must insure, then, the irrigation fluid reaching the upper part of the colon. This is best attained by having the patient's hips well elevated on firm pillows and to have him roll occasionally from his left to his right side. The same object may be secured by placing the patient in the knee-chest position. A liter of the quinin solution should be allowed to run into the colon twice daily. The strength of the solution at first should be 1-5000, gradually increasing it until it reaches 1-1000 or 1-500. In some cases we have given the patients at intervals an irrigation of a weak solution of hydrogen peroxid with apparent benefit. Colostomy has been recommended very highly by some in the intractable cases. It was only performed once in our series. The patient was almost moribund at the time of the operation and died shortly after.

Where the dysentery is complicated by hepatic abscess, the latter should be operated on at the earliest possible opportunity after a diagnosis has been established. Five of our 17 cases operated on recovered. While these results are fairly satisfactory they leave much to be desired. The earlier the operation the better the patient's prospects will be. The unsuccessful results after operation have, in many cases, been shown to be due to the fact that the abscesses are multiple and consequently only one abscess is evacuated, the others continuing to exert their injurious effects after operation. The operation is usually done in two stages in this hospital. The first operation is to promote shutting off the peritoneal or pleural cavities, depending on the seat of the incision. The second operation is for the evacuation of the abscess, and is performed a few days later. This delay, of course, is only permissible when the patient's condition will allow it. Rogers advocates very strongly a quinin solution of about 1 per cent. strength for irrigating out the abscess from time to time. He believes that the amebæ in the abscess wall are more quickly destroyed, thus allowing of a more rapid healing.

Where the abscess opens into the pleural cavity with the establishment of an empyema, free drainage must be established. When intestinal perforation occurs the experience with typhoid perforation in recent years leads one to hope that success might follow operation if performed very early.

SUMMARY.

In nearly fourteen years 120 cases of amebic infection have been admitted to the Johns Hopkins Hospital. Of these, 119 were cases of amebic dysentery or amebic abscess of the liver, the remaining case being one of amebic abscess of the floor of the mouth. Of the 120 cases 118 were admitted to the medical wards. During this time there were 15,817 medical admissions, the amebic dysentery cases constituting 0.74 per cent. of the cases. Of the 119 cases of dysentery, 82 were apparently contracted in Baltimore and 13 in the State of Maryland outside Baltimore, or a total of 95 cases within the borders of Maryland. The largest number of cases occurred in the third decade. The youngest patient was a child two years and eight months old, and the oldest a man of 71. A point of special interest is the comparatively large number of cases in children under 10 years. Eleven cases, or 9.4 per cent., occurred in the first decade, 6 of these belonging in the first hemi-decade. There were 108 males and 11 females. The series comprised 107 whites and 12 blacks, or a proportion of 9 to 1. The total ratio of whites to blacks in the hospital is about 7 to 1. A secondary anemia of moderate grade occurs. Occasionally there is a polycythemia. The average leucocyte count in the uncomplicated dysentery cases was 10,600. In the hepatic abscess cases it was 18,350. Hepatic abscess occurred in 27, or 22.6 per cent., of the cases. Nine of these ruptured into the right lung and 2 into the right pleura. Three opened into the inferior vena cava. In 10 cases there was a single large abscess in the upper part of the right lobe. In 8 cases there were multiple abscesses. Perforation of the colon with peritonitis occurred in 3 cases; and severe intestinal hemorrhage in 3 cases. Five cases were complicated by malaria; 1 by typhoid; 1 by pulmonary tuberculosis; and 1 by a strongyloides intestinalis infection. The agglutinative blood reaction with *Bacillus dysenteriæ* was negative in all cases tried. A marked feature of the disease is the great tendency to relapse. The mortality was high; 28, or 23.5 per cent., terminated fatally. Hepatic abscess is a serious complication, 19 of the 27 cases terminating fatally. Five were cured out of 17 operated on. Two of the hepato-pulmonary abscess cases were discharged very much improved. One abscess case did not remain to be treated. Quinin irrigations still seem to give the best results in the treatment of the dysentery.

THE TREATMENT OF ACUTE DYSENTERY.*

J. M. ANDERS, M.D.
Professor of Medicine and Clinical Medicine, Medico-Chirurgical College.
PHILADELPHIA.

The subject will be considered under three heads: 1. Regiminal Treatment; 2, Internal Remedies; 3, Topical Applications.

I. REGIMINAL TREATMENT.

The regiminal treatment, properly carried out in its various details, is potent to render the course of this affection distinctly milder and more favorable. Among the eminently important measures in bacillary dysentery I should regard rest in bed throughout the attack as deserving of a prominent place, and it should be rigidly enforced in all instances, not excepting the milder sporadic cases. As a means to conserve the bodily strength and energy, absolute repose is never uncertain in its effects; its extreme importance to the inflamed and ulcerated bowel, with a view to promoting resolution and the healing process, is universally acknowledged. The efficiency of rest in bed can be appreciably enhanced by constant, careful attention to the ventilation of the sick chamber. Fresh, pure air, without strong currents, is practically important as an aid in preventing the development of dangerous asthenia.

Too close attention to the diet and manner of feeding can not be paid. Certain dietetic principles need to be kept in view. For example, it must be recollected that concentrated, soft and liquid forms of food tend to favor constipation, whereas bulky, hard articles stimulate intestinal peristalsis.

Our aim in this disease is to minimize the intestinal contents, and thus, also, the amount of decomposable material that will reach the seat of the morbid changes. To reduce the putrefactive processes in the intestines, especially during the active period of acute bacillary

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

dysentery, an absolute liquid diet composed principally of milk and albumin water, is a prime requisite. The milk should be predigested and given in small quantities, and the dejecta carefully scrutinized; and the appearance of food remnants in the feces is an indication either for further dietetic restriction or a change of pabulum. Dieting must be systematically conducted. When not objected to, the albumin water is admirably suited to this disease in the early acute stage. If carefully carried out, a milk diet, however, is attended with the least degree of intestinal putrefaction. Nothing is more pernicious in its effects upon the local lesions than to overburden the much-enfeebled digestive organs.

It is doubtless true that the fats increase intestinal putrefaction, and must be allowed in relatively small amounts in this disease, if at all. This is probably also true of carbohydrates, although Bachman's experiments, contrary to the general teaching, show that they exert no marked influence on intestinal decomposition. Nutrients are of signal importance in supporting the vital powers, and may be preventive of dangerous asthenia. Finally, not all foods, even among the blandest and most nutritious forms, are equally well borne by the stomach, and several changes may be necessary during the course of a given case.

I have dwelt somewhat at length on the subject of diet in dysentery, believing that there is a lack of appreciation on the part of the general profession of its true value in the management of this disease.

Stimulants are required in the severer forms of endemic, and more especially epidemic, dysentery, to overcome the pronounced asthenic which often develops at a comparatively early period of the disease. Marked and even alarming circulatory enfeeblement may be met, and this calls for the free use of diffusible stimulants (e. g., champagne). In extreme adynamia, strychnin should be employed subcutaneously; and the timely, judicious employment of the normal saline solution is highly serviceable in similar cases. It has seemed to me that in our eagerness to find a special method of treatment (of which there are not a few from which to make a selection), agencies and elements whose efficiency has been satisfactorily demonstrated by the experience of by-gone generations of physicians, have been omitted from consideration in discussing the management of dysentery. An examination of the literature will confirm this opinion, so far as relates to the use of stimulants in this disease at least. The regimen, during the convalescing period, should receive much attention. Indiscretion in diet must be obviated; the too early use of fats, fruits and the coarser vegetables often cause a return of the dysenteric symptoms. The habits of the patient must be vigilantly looked after until full health is restored, and an abdominal bandage of wool is advised following an attack of dysentery, and may be warmly recommended.

The prophylactic measures applicable in the treatment of dysentery are much the same as those demanded by other micro-organismal diseases, notably typhoid fever, and need not be detailed here. Especial attention, however, should be paid to the disinfection of the excreta, while the drinking water must be both filtered and boiled. Unless a rigid system of disinfection of the stools be carried out during the prevalence of an epidemic, an infected individual contributes to the common source of contamination.

2. INTERNAL REMEDIES.

It is customary to speak of special methods of treatment by medicinal agents. This is unfortunate, since it tends to lead to neglect of other most important elements of the treatment. Pre-eminent among special drugs stands ipecacuanha, and although a most valuable agent in this disease, it can not be said to possess an abortive, or even curative, action; it is not a specific for dysentery. Says Hare:[1] "So far as we know, any influence which it possesses is brought about by reason of the fact that it tends to produce a rather profuse flow of bile in such patients, and the close connection which exists between the torpidity of the liver (to use a popular phrase) and congestion of this organ, with congestion of the colon, makes its employment under these circumstances more rational than would appear at first glance." Woodhull,[2] however, claims that "ipecac is not, as commonly supposed, a depressant or an evacuant, except in a secondary sense. Its primary action is that of a stimulant more directly of the organic nerve." He believes that this drug thus contracts the intestinal capillaries. Treatment, therefore, should be prompt.

R. Kobert[3] states that the antidysenteric action is supposed to reside in a glucocid, ipecacuanhic acid. It is probable that the use of ipecac has been less enthusiastically supported by clinicians in recent times than was formerly the case, because its mode of administration has not been of such character as to insure the highest efficacy of the drug. Kieffer[4] gives the following method, which has been adopted in tropical dysentery: "Nourishment of every description is withheld for three to four hours. Then 15 to 25 drops of tincture of opium are administered and a small sinapism applied to the epigastrium. In from twenty to thirty minutes, when the effect of the opium begins, from 30 to 60 grains of ipecac are administered in powdered form stirred up in one or two ounces of water. The patient lies on his back in bed with both eyes covered with damp, cool compresses. The pillow is removed. The patient is carefully enjoined to make no movement. If mucus gathers in the mouth and throat, a nurse, on sign from patient, removes it with a cloth or towel. If all these precautions are rigorously carried out, the patient retains the dose."

It requires at least two hours for ipecac to produce its effect. If it be vomited within an hour, the dose is repeated as soon as the nausea subsides. When all signs of nausea have disappeared the feedings are to be resumed. The next day repeat the dose of ipecac, diminishing it by 5 or 10 grains, and continue in this way for three or four days, using always the same precautions against vomiting. Kieffer feels that if administered in this way, ipecac will prove of value in the dysentery of the United States. Although aware of the fact that most authors recommend the massive dose, in my hands quarter-grain doses administered every half hour have in some cases seemed to be quite as effective, and in children the smaller doses are to be preferred. Strassberger[5] lauds ipecac highly in the treatment of the acute exacerbations of amebic dysentery, using one dram of the Rio article, with a full dose of opium, twice daily. The effect was prompt and permanent, and in only one instance did a real relapse occur. Upon further investigation and observation he found that while it may be a specific in amebic dysentery, it has little or no effect on the bacillary forms.

The use of saline laxatives in the treatment of dysentery is generally adopted. The best preparation is

magnesium sulphate, which produces an eliminative effect, depletes the intestinal mucosa, and at the same time inhibits undue peristalsis. It is best administered in doses of one dram, diluted, every hour until free purgation is induced. This is followed by the generous exhibition of acid. aromat. sulphuric., which is given partly for its astringent effect and partly to render the intestinal contents acid. It has been shown by Cunningham of India, with reference to amebic dysentery, that if the contents of the intestines are alkaline, the amebæ thrive and multiply, while conversely, if the intestinal matter is rendered acid, their multiplication ceases for want of a suitable medium. The combined saline and acid method of treating dysentery rests on a most rational basis. I have, however, found and elsewhere expressed the opinion that if saline purgatives are employed at a late stage of the affection, or even after the full development of a given case, they are invariably attended with baneful effects. Richmond[6] also observes: "It is of the utmost importance that cases in which the sulphate of magnesium or sulphate of sodium should come under treatment early in the attack, before much ulceration has taken place, otherwise the septic absorption continues. In some cases treated by this method at Duelfontain, little or no improvement accrued, and the "patient died in a condition of toxemia, with rapid failing pulse, delirium and profuse diarrhea, with much painful tenesmus." Opium in some form, preferably as Dover powder, is promptly effectual in meeting certain leading systematic indications, as pain irritability, restlessness and undue peristalsis. For intensely distressing tenderness, either an opium suppository or laudanum by enema exercise a beneficial effect. The preparations of bismuth are valuable, particularly in the milder sporadic cases, and in the advanced stage of the severest forms; they may be advantageously combined with Dover powder and an antiseptic substance.

Phelm,[7] who has had an extensive experience in the treatment of this disease in Africa, advises the successive use of purgatives, calomel and subnitrate of bismuth. A suspicion of dysentery calls for 30 grams of castor oil. If the case be one of dysentery, calomel is given after twelve to eighteen hours. At the end of three days, calomel is succeeded by bismuth subnitrate, which, in turn, is kept up for three or four days, or until the stools become solid again. It may be questioned whether any of the intestinal antiseptics exercise a potent influence; and it may be safely assumed that they are without the power to destroy the infecting micro-organism. The antiseptic care of the intestinal tract in bacillary dysentery, however, should be one of the aims of treatment, and guaiacol, salol and the preparations of naphthol are the agents of choice for this purpose. They may be combined either with the ipecac or salines, or with both. Richmond,[8] during an experience of the treatment of dysentery, found that none of the recognized methods were infallible, and the use of sulphur in the treatment of this complaint was suggested to him on the analogy of the treatment of anthrax by sulphur, as advocated by Mr. Arbuthnot Lane.[9] He had under his care in the Imperial Yeomanry Hospital at Pretoria, 20 acute cases and 10 cases of chronic diarrhea following attacks of acute dysentery. All the acute cases were treated with sulphur and Dover powder, and the chronic cases with sulphur alone, and in every instance a cure resulted. The ameba was carefully searched for in all of Richmond's cases, but was never found, and he believes it to be a justifiable speculation that the dysentery of South Africa was, like that of Japan and the Philippines, due to the Shiga bacillus. This observer prescribed 20 grains of sublimed sulphur combined with 5 grains of Dover powder four-hourly in the acute cases, and a like dose of sulphur alone in the chronic diarrhea resulting from acute attacks. The signal value of this remedy has been confirmed by the experience of other competent clinicians, both abroad and in this country. Although the exact mode of action of the sulphur is unknown, it is probable that the resulting sulphuretted hydrogen and sulphur acids inhibit the growth and propagation of the *Bacillus dysenteriæ*. Stengel has observed the same curative effect in amebic dysentery, and it is quite reasonable to suppose that the modus operandi of its action is similar in this form to that of bacillary dysentery. This remedy is strongly advised on theoretical grounds, and in view of the brilliant results already reported, is worthy of a more extended trial than has as yet been accorded it. It will probably be found to be best suited to protracted or chronic forms of the complaint. Dabney has pointed out the eminently important fact that the existence of certain complicating conditions, as malaria and various intestinal worms, may occasion non-success in attempts at treatment, unless recognized and met by the use of quinin or anthelmintics according to the given case. Failure of the ipecac treatment may also be due to the unreliability of its preparations.

Another method of treatment is by the use of antidysenteric serum. Gay[10] has prepared vaccines of uniform activity, and by means of which he could protect guinea-pigs from a multiple fatal dose of living dysentery bacilli, and also produce in the horse an active, immune serum. Gay thinks that a useful serum therapy of bacillary dysentery and of certain forms of the summer diarrheas in infants (the latter having recently been shown to be due to the *B. dysenteriæ*) is rendered highly promising. Shiga has successfully employed a serum which he himself has prepared. It is both protective and curative, but not as yet available for general use.

3. TREATMENT BY TOPICAL APPLICATIONS.

The treatment of dysentery by high intestinal irrigations is doubtless of value, but quite a few recent writers are not ardent advocates of the use of large enemata in acute bacillary dysentery, believing that they may cause atony and weakening of the coats. Astringent and antiseptic solutions are used for this purpose; they must be weak, otherwise the tormina and tenesmus—distressing features of the disease—will be materially increased. The method is better adopted to the more chronic forms of dysentery, the amebic variety in particular. In the latter, a warm solution of quinin (1-2,000, 50-5,000) is almost universally acknowledged to be more or less efficacious. It may be questioned, however, whether the amebic form is curable by known methods of treatment. In the milder forms of acute bacillary dysentery, copious enemata are unnecessary. If employed in this class of cases, the same precautionary measures must be taken as in the severe types of the disease.

Among the remedies thus employed are silver nitrate, strength of solution (gr. ss. to 1 ad ℥i); salicylic acid (1 to 2 per cent.); tannic acid (½ to 1 per cent.); zinc. sulpho-carbolate (gr. i-ii ad ℥i); and mercuric chlorid (1-6,000).

9. The Medical Week, Dec. 8, 1891.
10. Univ. of Penna. Medical Bulletin, Nov., 1902.

It has been my custom to alternate an astringent and antiseptic solution, administering a copious clyster at twelve-hour intervals.

The mode of giving the irrigations is of vital importance. A fountain syringe should be employed, and as shown by the experiments of Hare and Martin; the pressure should never exceed two or three feet. Intestinal lavage must be a slow process in order to be successful, and to this end the flow should be interrupted at short intervals. The patient during the enemata should assume either the dorsal position or that on the left side, with the hips elevated; or if he be not too ill, he may be turned from side to side during its administration.

In conclusion, I would emphasize the fact that it is impossible to indicate a special mode of treatment that would be suitable for all cases of dysentery since each case, whether of the bacillary or amebic variety, presents certain individual peculiarities. The therapeutic measures must vary also with the particular stage of the affection and the previous condition of health of the patient.

DISCUSSION

ON PAPERS OF DRS. MASON, KNOX, BURNS, HARRIS, FUTCHER AND ANDERS.*

Dr. Alexander Lambert, New York—This is not a common disease in the North. Still, it is not uncommon among transients going through New York and who land in Bellevue Hospital. Some years ago I was surprised to find cases of amebic dysentery developing in people not 25 miles from New York; I have had four such cases in the past five or six years. It has been stated that liver abscesses were more frequent in the North than in the South. So far as a limited experience in a number of cases of amebic dysentery is concerned I have seen abscess develop in a large number.

I have found that high enemata given one week, and quinin the next week, and silver once or twice a day, have given me better results and quicker improvement than followed when I persisted in quinin or silver. In the more chronic cases I have given 1-500 bichlorid solution and run it down to 1-1000 with beneficial results. Salol and castor oil seem to give more satisfaction with some patients. Most of these cases have gone out of the hospital cured unless they died of liver abscess.

In all these cases of amebic dysentery there was one symptom that I have been unable to find mentioned in any textbook, viz., the severe amount of pain in the muscles at night; painful cramps in the muscles were found in every case of amebic dysentery. In the other cases of dysentery this was not complained of. I should like to hear from the Section on this symptom.

Dr. T. S. Dabney, New Orleans—At first I used sulphate of magnesia, but experience has taught me that sulphate of soda by reason of its action on the liver is far more efficacious. I also wish to state that the combination I use has a little morphin added, 1/6 to 1/32 of a grain to the dram; there is also dilute hydrochloric acid and peppermint water, and this combination acts well. If you take six cases of dysentery and use sulphate of soda in three, and sulphate of magnesia in the other three, you will not use sulphate of magnesia again. In conjunction I use acid drinks of dilute sulphuric acid, or nitrohydrochloric acid. All my patients drink this all the time. Experience has taught that the bacillus of dysentery seems to thrive poorly in acid and acid medium; it seems to require an alkaline medium, hence acidulated drinks inhibit the growth of this bacillus.

While in Colombia, South America, in the summer of 1892, I was asked by Dr. Angoula, a native Colombian physician, a close observer of the endemic diseases of his country, to visit the village of Rio Frio, situated in the midst of vast banana haciendas, where a disease, characterized by severe intestinal hemorrhage, was at that time prevailing. In almost every thatched hut we found patients suffering from profuse bloody discharges at frequent intervals. A moderate amount of fever, but not much tormina or tenesmus was present. So great was the loss of blood that the patients seemed exsanguinated. On being asked by the Doctor for the diagnosis and treatment, I politely declined either, and remarked I was the student and he the teacher. His diagnosis was intestinal paludic fever and his routine treatment one gram of the sulphate of quinin dissolved in water acidulated with dilute sulphuric acid, this to be repeated every four hours until the character of the stools markedly changed. On our second visit, six hours later, we found the diagnosis verified by the treatment, for never in my professional life before had I seen such immediate and happy results follow so promptly on the administration of any remedy. I am inclined to believe the acid medium played an important part in the cure.

Dr. T. J. Moore, Galveston, Texas—I believe that there is not only amebic but also bacillary dysentery where I live. During the past four years we have carefully examined every malarial fever case, and, as a result, I am not ready to admit that we have malarial dysentery. I have treated during the past four years several hundred cases of malarial fever and associated with many there has been dysentery, but on closer investigation we have found, in probably all of them, some other cause for the dysentery than the malarial infection. I would rather regard dysentery as one of the symptoms of malarial fever seen occasionally. Hemoglobinuric types of fever with dysentery seem to be more common. We must admit that there is some gastrointestinal disturbances in many cases, but I am not ready at all to admit that we have malarial dysentery. Many cases of amebic dysentery get better on quinin and some better without quinin. During the past three years, at my suggestion, in the wards of the hospital we have been using the fluid extract of chaparro, a Mexican shrub. In the series of cases in which this drug was used, some ten or twenty, there was a rapid disappearance of the dysentery, and also of the amebæ from the stools. This drug is well worthy of trial.

Dr. Lambert has referred to cramps in the muscles of the arms and legs; this is especially true in the severe and acute cases where you find a great number of these amebæ, many containing red blood cells. In the severe cases the amebæ show a disposition to collect within themselves a large number of red blood cells. In the acute form there is another feature, the acute swelling of the mucous membrane which may cause a complete occlusion of the intestines.

Dr. Walter Shropshire, Yoakum, Texas—The cause of this disease has been to me an enigma for many years. Three years ago I had a case in a child nine months old. Severe symptoms were referable to the lower rectum and the disease progressed rapidly. An examination of the feces disclosed amebæ which contained red blood cells. Irrigation of the rectum and colon with quinin caused a disappearance of the ameba. When first examined I found the colon bacillus in large quantities. I called another physician in and he agreed with me in my diagnosis. The colon bacilli persisted, and the disease continued until the child began to vomit. In the vomit were found numbers of these bacilli, but no amebæ. At the autopsy, macroscopically, there was noted the characteristic undermining ulcers of the amebic dysentery. Further up in the tract were found bright red congestion of fresh inflammation. Microscopically there were found the same bacilli throughout the intestinal tract, in the mesenteric glands, liver and spleen. We then decided that this bacillus was the cause of the disease. Specimens were sent to Dr. Smith of Galveston, and he agreed that they were the colon bacilli, but said they were harmless in the intestinal tract. I am firmly convinced, though, that they were the cause of the disease. Since then I have not been able to discriminate between the two, Shiga's and the colon bacillus, and shall appreciate an accurate method of doing so.

Dr. Charles F. Mason, Ft. Sam Houston, Texas—A great many soldiers come to me after they have passed through

* The papers of Drs. Mason and Burns appeared in The Journal, July 25: that of Dr. Knox, July 18.

several hospitals and after they have been recommended for discharge on account of disability; now, after a little experience with the following treatment, we find that these men can be much benefited. First, an anesthetic is given and the sphincter thoroughly dilated in order that a careful examination of the mucous membrane of the rectum can be made; almost always we find a little ulceration in the rectum within five or six inches from the sphincter. These ulcers are apt to be undermined, forming little pouches in the mucous membrane in which a probe can be introduced or hooked, and in which foreign matter as it comes down the bowel may gain entrance. Such ulcerations are treated by slitting them down to the bottom and curetting them or touching them with pure carbolic acid, or both. The bowel is then washed with a normal saline solution and the patient placed in bed and kept quiet on a liquid diet and preparations of milk. Irrigation with normal saline solution are used thereafter once or twice a day. Every case with one exception has been cured and returned to duty.

DR. J. H. M. KNOX, Baltimore—The work was begun last summer at the Thomas Wilson Sanitarium with much skepticism as to the relationship of the Shiga bacillus to the diarrheal cases under treatment. The dysentery organism was isolated in case after case which seemed to be quite identical clinically with the several types of intestinal disorder in infancy which are grouped together as summer diarrhea. The claim is not made that every case of diarrhea in infancy is produced by this bacillus, but our experience at Baltimore last summer would certainly indicate that a large number at least of both the acute and chronic diarrheal disorders of infants are associated with *Bacillus dysenteriæ* (Shiga). It is to be emphasized that the isolation of this organism from the stools or intestinal tract requires some special skill and a bacteriologist well trained in other lines may easily overlook the specific bacillus, as indeed must have been repeatedly done.

It is to be hoped that during the coming summer a very large series of cases will be carefully studied in many localities that it may be determined to what extent the Shiga bacillus is responsible for the widespread infant epidemics which occur each summer. I should like to urge that all those who see these cases and have access to bacteriologic laboratories familiarize themselves with the special technic necessary in isolating the Shiga bacillus and then join in the effort to assist in the bacteriologic study of summer diarrhea. We shall be glad to send cultures from the sanitarium to any who wish to familiarize themselves with the organism.

DR. WM. BRITT BURNS, Memphis, Tenn.—I do not think we are any nearer a definite knowledge of the etiology of dysentery. I am aware that most all authorities at the present time do not agree that malaria has been a causative factor in dysentery. I am also aware that some cases of bacillary and amebic dysentery occur when in unison with the malarial parasite in the blood, but I do not find that those cases respond to treatment rapidly, and I do not believe that the ordinary bacillary and amebic dysentery would respond so readily to the treatment, as I have seen many cases do under the treatment ordinarily used in malarial disease.

DR. H. F. HARRIS, Atlanta, Ga.—I wish to call attention to the treatment of amebic dysentery with hydrogen dioxid, concerning which, I observe, nothing so far has been said. When, in 1891, I saw my first case of this disease, I used the treatment first recommended by Loesch, and since lauded by various writers, which consists in injecting quinin solutions into the large intestine of those afflicted with the malady in question. Although the patient showed absolutely no improvement, I employed the same treatment in the next nine cases that came under my observation, and not in a single instance was there any appreciable effect produced. This led me to make some investigations as to the power of sulphate of quinin to kill the *Amœba coli*, and I was much astonished to find that this substance seemed to exert but little influence on these parasites. In one instance the amebæ remained alive at the temperature of the room for more than twenty-four hours in a supersaturated solution of this substance. It was thus clear that quinin sulphate could not be relied on to produce the death of the amebæ, particularly when they are embedded in the tissues, nor can this substance destroy the numerous bacteria that lie in and around the ulcers and are doubtless largely responsible for many phases of the clinical picture in this disease. Failing to get any results from the quinin injections, I tried almost everything that has been recommended in the treatment of chronic dysentery, and never succeeded in securing results in any way satisfactory. Finally, at the suggestion of a student, I used daily injections of hydrogen dioxid, diluted with water from four to six times, with the result that there was an immediate and most striking amelioration of the symptoms in almost every instance—in every case, I believe, where the solution was brought in contact with the lesion. A remarkable result of this treatment is that blood is never seen in the stools after the first injection in instances where the medicament acts properly. The treatment is continued daily for a week, and after this the number of injections are gradually reduced in number until at the end of from four to six weeks no more are given. Especially at first the injection sometimes causes severe pain, and when this is the case it is well to administer morphin an hour before the treatment is given. It is absolutely necessary that the patient be placed on a strict milk and egg albumin diet, and that he should remain in bed for from two to four months. Occasionally patients recover when these precautions are not taken, but it is unusual. I have only seen muscular cramps in bad cases.

DR. T. B. FUTCHER, Baltimore—I do not recall that any of our patients complained of muscular cramps. This symptom may occur in the southern states, where a severer type of the disease probably prevails.

We have to modify our views considerably concerning the bacteriology of the amebic hepatic abscesses. Cultures have shown that the abscesses are sterile in a much smaller percentage of cases than was formerly believed to be the case. The more frequent organisms are the *Staphylococcus pyogenes aureus* and the *Bacillus coli communis*. The *Streptococcus pyogenes* was present in three of our cases and the *Micrococcus lanceolatus* and *Bacillus pyocyaneus* once each.

In the line of treatment quinin irrigations yielded the best results. The success of this treatment depends largely on the way the irrigations are given. The object sought for is the assurance that the quinin solution reaches the cecum and ascending colon, where the ulcerations are most extensive. The relapses are due to the failure of the drug to reach the amebæ buried in the deeper layers of the submucosa. In one case an infusion of a Mexican herb which had been sent us was tried with fairly satisfactory results.

DR. JAMES M. ANDERS, Philadelphia—It is probably advisable to reiterate the importance of the benefit to be derived from absolute rest until all of the acute symptoms have subsided, whether for a shorter or longer period. The question of diet in this disease is one to which too little attention has been paid. I believe that ipecacuanha is the best single remedy for treatment of this disease, but it is not a specific, and not all patients can take massive doses. One-fourth to one-half grain doses at short intervals will give excellent results in many cases. Saline treatment should not be employed in advanced cases, but only when the patients come under observation early; as the result of a considerable experience with this method I find that if employed in the advanced stages of dysentery it aggravates rather than benefits the condition. The sulphur treatment should especially be given a trial in those cases in which ipecacuanha fails. This agent seems to be well adapted for the subacute or chronic forms; better than to the acute, bacillary form of the disease.

Cathell on Medical Societies.—Independently of the benefits and improvements accruing to the members of medical societies individually, they give a sound and healthy tone to the entire profession, stimulate the growth of medical science, and also generate and keep alive a genuine professional and brotherly spirit that tends to minimize all that is unprofessional.—Cathell.

RECENT INVESTIGATIONS BEARING ON INFECTIOUS DISEASES OF UNKNOWN ETIOLOGY.

LUDVIG HEKTOEN, M.D.
CHICAGO.

(Concluded from p. 409.)

Bacteriologic and microscopic examination of the blood has given no constant results. Nevertheless the injection of a few drops of blood invariably causes death in two or three days. Indeed, the mere insertion of a needle into the blood suffices to carry over sufficient virus to cause death. Fatal infection by way of the stomach follows the mixing of a few drops of blood with the food, and the clearest serum is as infectious as the whole blood. By inoculating a series of animals, one from another, Centanni shows that it does not concern a toxin or enzyme, but a viable virus capable of endless reproduction. He further found that the infectious agent passes through Berkefeld and Chamberland (F) filters in virulent form. Maggiora and Valenti find that the Chamberland filter K under a pressure of 1½ atmospheres holds back the infectious agent.

Lode and Gruber made the observation, confirming it by frequent repetition, that the specific cause, whatever its nature may be, passes through Berkefeld and Chamberland filters. Successive inoculation through a series of animals convinced them also that the cause is one capable of multiplication. Hence the disease is the result of the infection. In a subsequent article Lode states that the filtrates of Chamberland (kind of cylinder not stated) and Hauser filters were not definitely infectious and that the Pukall filter gave uncertain results. Berkefeld filtrates, however, were always as virulent as the unfiltered material.

As stated, culture experiments have not been successful. Various methods have been employed, including Nocard and Roux's intra-abdominal collodion sacs (Centanni).

Spontaneous infection of eggs does not seem to occur. The feces are probably not infectious in the most acute cases, but may be so in the subacute. Maggiora and Valenti declare that the secretions of the nose and pharynx are very virulent in the diphtheroid form of the disease. The exact manner in which spontaneous infection takes place is not clear, but Centanni is inclined to exclude air, dust and insects from the list of possible modes of infection.

While many birds are susceptible to the disease, rabbits and dogs appear to be immune. Young pigeons develop a peculiar labyrinthine vertigo, the semi-circular canals showing inflammatory changes, tending to sclerosis, and designated by Centanni as semicirculitis specifica.

Centanni found that the virus resists the temperature of the incubator (37.5), but heating to 60 C. for one hour destroys the infectiousness of virulent blood. Drying also destroys the virulence, but in tubes closed by melting the ends blood may remain virulent for a long time. The usual disinfectants destroy the virus quickly.

Lode states that decomposition and the admixture of various organisms destroy the virus with marked promptness, but it may remain active for twenty to thirty-three days in the unopened bodies of dead chickens, and dried material from the liver, spleen and brain remains virulent for about four weeks. Sterile filtrates remain active for several days. He finds that heating to 80 C. for thirty minutes destroys the virulence, but that strong sunlight playing directly on the dried infectious material did not render it harmless. Successful efforts to obtain immunity have not been made as yet.

The disease that Maggiora and Valenti had occasion to study corresponded closely to the clinical and anatomical descriptions by Perroncito and Rivolta of the disease named by them exudative typhus, which name Maggiora and Valenti believe ought to be retained. They show that dilutions of the blood up to 1 to 500,000 cause death in doses of 4 c.c. injected intraperitoneally. In the case of filtrates of blood emulsions 4 c.c. of a dilution of 1 to 160 represented the smallest fatal dose. Blood and exudates removed immediately after death or during the last moments of life remained virulent for forty-five days preserved in Pasteur pipettes in the dark. The meat of diseased fowls is probably not dangerous for man, but Maggiora and Valenti assume a conservative attitude in regard to this part. The virus in the epidemic studied by Maggiora and Valenti is, therefore, similar in most respects to that studied by Centanni, but the latter proved pathogenic for ducks and pigeons (Tauben), whereas the former proved harmless for these animals.

Albert Dubois[16] has observed a similar disease quite as fatal in Belgium, the infection being introduced with chickens imported from Italy. Filtrates of emulsions of the liver passed through Chamberland bougies proved virulent in a high degree.

Maggiora and Valenti[17] describe recently an infectious disease of birds (Turdus merles) caused by a microbe that passes Berkefeld filters.

7. *Rinderpest.*—Nicolle and Adile Bey[18] show that the virus of cattle pest ("peste bovine," "Rinderpest") sometimes passes through filters that are ordinarily considered bacteria-proof and sometimes not. This disease is caused by an as yet unknown virus, unknown either because invisible or incultivable, or both, by means of our present methods. Its variable behavior in regard to filtration is explained in part by the kind of filter used. Berkefeld filters are more permeable than the Chamberland filters, and of the latter the cylinder F is more porous than cylinder B. Again, the character of the fluid containing the virus plays a part. Thus a serous fluid appears to hinder the passage of the virus (shown by Nocard and Roux to be true also in the case of peripneumonia) and dilution of such fluid appears to reduce so materially the virulence of the virus as to explain the harmlessness of resulting filtrates. For control of the results of filtration of unknown virus and their significance these authors recommend the use of hydrant water, which they say commonly contains vibrios that have the power of passing through many filters. There are certain facts that indicate that the virus of bovine pest may occur within leucocytes: The blood of infected animals is the most virulent of all fluids in their bodies, and Kolle has shown that the virus is carried down by centrifugalization of both laked and unlaked blood. In blood laked by means of distilled water the leucocytes are regarded as the only elements that escape destruction. The absence of local lesions at the site of injection is also in harmony with the idea that the virus is intraleucocytic. And if the virus is contained within leucocytes it is easy to understand why it does not pass through filters freely and regularly.

8. *Sheep Pox.*—Borrel[19] finds that the virus of clavelée, a pustular disease of sheep not unlike smallpox, and

19. Compt. rend. de Soc. de Biol., 1902, liv, 59 61.

characterized by lesions of the skin, passes through Berkefeld filters, the filtrate being sterile when inoculated in broth, but virulent to sheep. He found, further, that the virus passes through bougie F4 and F5 of the Chamberland filter, but not through bougie F. Borrel regards the inclusions described by Bosc within cells in the cutaneous pustules and in cellular foci in internal organs in clavelée as leucocytes, and he holds, further, that the filterability of the virus is not in accord with the protozoan theory of this eruptive disease. The fact that the virus passes through filters can not, however, be regarded as conclusive proof that the inclusions are not protozoan in character, because it is possible that spore forms may be so minute as to be filterable.

Borrel[20] further points out that water vibrios sometimes pass through filters, especially when the process of filtration is prolonged. Some of these organisms are so minute as to reach the limits of the visible. He also points out that it may take several days at the room temperature before the filtrates are rendered turbid by these water organisms, subcultures in bouillon remaining sterile. Borrel notes further that protozoön, *Micromonas mesnili,* once passed a Chamberland filter.

9. *"Mosaic Disease" of Tobacco.*—Beijerinck[21] has studied the virus of an economically important disease of the tobacco plant ("Mosaik s. Fleckenkrankheit"), marked by decolorization and necrosis of the leaves. This disease is contagious, and is caused by an interesting, filterable virus that can not be seen or cultivated in the usual way. It remains virulent for six months after heating to 70 C. According to Ivanowski,[22] diseased leaves remain infectious after conservation for several months in 95 per cent. alcohol. In discussing the question whether this virus is corpuscular or dissolved ("contagium vivum fluidum"), Beijerinck seems to conclude that it is dissolved and fluid because when infectious material is deposited on the surface of agar, diffusion of the virus evidently takes place without visible change of the agar, the part below the surface becoming infectious, but without any change in the color of the medium or its refraction of light. It is open to question whether this diffusibility of the virus can be regarded as evidence of its being fluid. A minute organism might be able to penetrate into the depths of the agar. When the virus is inserted in the ground in the vicinity of tobacco plants the disease soon makes its appearance in them.

Evidently there is room for further investigation into the nature of this virus.

10. *South African "Horse Sickness."*—Macfadyean[23] found that mixtures of virulent material from horses suffering from "horse sickness" (a disease killing the majority of the horses recently imported into certain districts of South Africa), filtered through Berkefeld and even Chamberland B filters, proved fully virulent and infectious. According to Roux, Macfadyean is the only one to report successful filtration of "invisible" virus through the Chamberland bougie B. Nocard[24] found that the dilutions of the blood remain virulent after passing through Berkefeld filters, but not after going through the Chamberland F. Macfadyean draws the conclusion that the microbe of "horse sickness" is smaller than those of peripneumonia and of foot and mouth disease, which do not pass through Chamberland B.

24. Quoted by Roux, Bulletin de l'Inst. Pasteur, 1903, i, 7-12 and 49-56.

11. *Epithelioma Contagiosum.*—Marx and Stickler[25] investigated the etiology of the so-called "epithelioma contagiosum" of chickens and other fowls. They show that the disease is readily inoculable, and that the virus passes through Berkefeld filters, but not through porcelain filters (Chamberland F). The virus proved to be resistant to drying and exposure to full daylight for several weeks and to a temperature of —12 C. for five weeks. It also withstood heating to 60 C. for three hours, and to 100 C. for one hour if dried and enclosed in vacuum tubes. It may be preserved in glycerin, but 2 per cent. carbolic acid destroys its power. Immunity is produced by a single, well-marked attack. The virus of the diseases in pigeons (Taubenpocken) is translatable to chickens, but it can not be successfully transferred from chickens to pigeons. In connection with this subject reference may be made to the interesting and important work of Leo Loeb and of Herzog on transplantable malignant tumors of sarcomatous nature in white rats. In a recent article[26] Loeb describes a number of experiments on material from these tumors, and in connection with the matter now under discussion it is especially interesting to note that all of his experiments, like those of Herzog, with filtrates of suspensions from tumors passed through Berkefeld filters, gave negative results. In no case did injections of such material cause the development of tumors.

Summary of Filtration Experiments.—From the results of filtration experiments certain infectious diseases of unknown etiology may be separated into two broad groups: (*a*) those caused by filterable virus, namely, foot and mouth disease, peripneumonia, rinderpest, sheep-pox, chicken typhus, horse sickness, epithelioma contagiosum of fowls, and yellow fever; and (*b*) those caused by non-filterable virus, namely, hydrophobia (?), vaccinia and smallpox.

Of the filterable viruses only that of peripneumonia has been cultivated; the presence of the others has been evident only by the pathogenic action of the fluids used.

This enumeration shows that the application of filtration to the study of transmissible diseases combined with experiments on susceptible animals or human beings, has given the investigator most valuable information that in some cases, no doubt, has spared him many fruitless tasks. The demonstration that the causes of yellow fever, of foot and mouth disease, etc., exist in virulent form in bacteriologically sterile filtrates, so far as demonstrable at the present time, would seem to show that it does not concern elements that can be studied with much hope of success by ordinary microscopic and bacteriologic methods. Thus the claims that yellow fever, for instance, is caused by *B. icteroides* are bereft of all support.

INTERPRETATION OF FILTRATION EXPERIMENTS.

We are hardly in position to affirm that size is the only factor that determines filterability or non-filterability of a virus. Attention has been called to the variable behavior of the virus of bovine pest in the filtration experiments of Nicolle and Adile-Bey. Here the kind of filter, the thickness of the wall, and the character of the fluid were found to play an important part. It was pointed out, too, that an intraleucocytic position of the virus would explain the failure to pass through some filters. Then, again, of late have been described visible bacteria that pass through filters such as the Berkefeld and Chamberland, filters originally regarded as im-

25. Deut. Med. Wochenschr., 1902, xxviii, 892-895.
26. Virchow's Archiv, 1903, clxxii, 345-368.

pervious to visible bacteria. Whether this permeability depends on special peculiarities of the organisms in question, such as mobility, elasticity and compressibility, or on special peculiarities of the filters used, has not been determined. In connection with certain experiments in filtering fluids rich in saprophytic organisms, von Esmarch encountered a minute spirillum (*Spirillum parvum*) that readily passes through Berkefeld, Pukall and Reichel filters, as well as Chamberland cylinders (F. controllée). This avirulent organism measures 1 to 3 mikrons in length, and from 0.1 to 0.3 mikron in breadth, closely approaching *B. influenzæ* in size. It is actively motile. I have already referred to the fact that Borrel also met with water vibrios that readily passed certain filters.

William B. Wherry[27] corroborates the findings of Theobald Smith in 1899 that a small, active bacillus causing pneumonia in guinea-pigs passes through Berkefeld filter No. 5. This bacillus is 0.5 mikron wide and about 0.7 mikron long. It did not pass through the larger Berkefeld No. 8, nor Chamberland bougie F. Both this organism and *B. coli communis* grow through filters quite rapidly. Hence a virus passing through Berkefeld filter No. 5 is not necessarily ultramicroscopic.*

The influence of consistence and adaptability on the part of cells subjected to filtration is shown well in the following observation by Bunge (Physiological Chemistry): "The large blood corpuscles of amphibia may be collected in the filter (that is ordinary filter paper), but not those of mammals. This is not due to their minuteness, for they are far larger under the microscope than, for instance, the crystals of a precipitate of sulphate of barium or oxalate of lime, which do not go through the filter. The red corpuscles pass through the filter because, owing to their soft and yielding consistency, they adapt themselves to the form of filter pores." It would be quite reasonable to infer that invisible organisms passing filters are endowed with motility.

Lode and Gruber advanced the idea that bacteria and similar bodies are held back by porcelain and infusorial filters by virtue of force of attraction, rather than on account of the smallness of the pores, whose diameter they claim generally exceeds the size of ordinary bacteria. They further suggest that the invisible bodies that pass through in the case of the various filterable viruses exist as semi-fluid masses, rather than as corpuscular elements like bacteria, and they even go on to intimate that such viruses may be in solution—Beijerinck's "contagium vivum fluidum"—acting after the manner of enzymes, yet capable of reproduction, but only to abandon the idea again because of the absence of demonstrable analogies. It seems to me that the fact that practically all known filterable viruses pass through the Berkefeld filters, whereas many are held back by candles of the Chamberland system, speaks against their theory of surface attraction because Berkefeld filters, being composed of infusorial earth, contain especially extensive surfaces. And then, why should the force of attraction be suspended in the case of the different materials employed in the filtration of these unknown viruses? After all, the size of the pores, being now smaller and again larger than known bacteria, and not at all of uniform diameter, and the physical character of the elements subjected to filtration would seem, for the present at least, to offer more generally applicable explanations of the results of filtration experiments.

And as it is not justifiable to assume that cellular life necessarily ceases at the limits of visibility, it does not seem to me that these experiments with filterable viruses must needs lead to the establishment of new and strange theories of the nature of the contagious elements. There is a relatively far jump between the size of the smallest visible objects and the estimated size of molecules, which again vary greatly in respect to size, and within the ultramicroscopic limits thus defined there may exist a true "mundus invisibilis," some of the inhabitants of which, endowed with metabolic and reproductive faculties, certainly may be the causes of transmissible diseases.

On the other hand, the non-filterability of certain unknown viruses—hydrophobia, variola, vaccinia—may be in itself alone insufficient reason for regarding the particular organisms in question as large enough to be visible. Attention has been given to the possibility that in the case of rinderpest the unseen virus at times may be non-filterable because surrounded by cellular protoplasm. In the case of variola and vaccinia Park's experiments with crushed material indicate, however, that other reasons must be sought for their non-filterability than intracellular position. The facts that Pukall filters hold back or destroy certain complements in serum (Ehrlich and Morgenroth and others), and that many serums with difficulty are filterable when undiluted, indicate that in filtration factors are at work that we now understand but poorly. The filtration of colloidal solutions merits further study, and the entire technic of mineral filtration should be exhaustively investigated.

ULTRAMICROSCOPIC SAPROPHYTIC ORGANISMS.

The probable existence of ultramicroscopic infectious agents has turned the attention to the question whether ultramicroscopic saprophytic forms might not exist also. As pointed out by Lode and Gruber and by von Esmarch,[28] it is rather remarkable that such forms have not been encountered as yet in view of the large amount of work done with various forms of bacterium-proof filters. Von Esmarch's experiments in this line consisted in the filtration of various mixtures, rich in bacteria of all kinds, like ditch water, vegetable infusions, decomposing urine, sputum, parts of cadavers, fecal matter, etc. The clear filtrates thus obtained were used for culture experiments on a large assortment of nutritive solutions kept under aërobic, as well as anaërobic conditions. But his efforts in this way to demonstrate the presence of ultramicroscopic forms all failed. All his mixtures, even after months of observation, remained either clear, or if turbidity or sediments formed, subcultures yielded no indication that this was due to living organisms capable of proliferation. This apparent failure he would attribute to our ignorance of the conditions essential for the life and multiplication of ultramicroscopic or invisible organisms, the actual existence of which he would not deny on the strength of these experiments. In this connection it is interesting to note that virulent filtrates of infectious materials derived from diseases just considered (except peripneumonia) have not shown any macroscopic or microscopic sign of the presence of living organisms so far as that is determinable by present methods. In our laboratory at Rush Medical College Dr. Friedman repeated some of

27. Jour. Med. Research, 1902, viii, 322-328.

* It follows that filtration experiments must be controlled most carefully. Löffler and Frosch used as control *B. florescens;* Nicolle the vibrio of chicken cholera, and Borrel certain water vibrios. Further, that in view of the fact that bacteria may "grow through" filters, all filtration of unknown virus must be rapid.

28. Centralbl. f. Bakt., 1902, xxxii, 561-569.

the experiments made by Esmarch, obtaining only negative results. Whether virulent filtrates contain particles of ultramicroscopic size whose presence may be rendered evident by means of physical methods, such as that described by Siedentopf and Zsigmondy,[29] has not been determined as yet. By this method an intense oblique illumination falls on a small field under certain conditions so that ultramicroscopic particles refract light enough into the objective to produce images, or rather luminous points. The authors succeeded in this way to render visible minute particles of gold incorporated in glass that with the highest magnification of a Zeiss microscope appeared perfectly homogeneous when illuminated in the ordinary way. Mouton[30] has suggested the use of the apparatus in bacteriology. (The use of the method in studying pathogenic agents too small to be seen is spoken of also in an editorial in THE JOURNAL, July 11, 1903, p. 104.)

CONCLUSIONS.

1. Clinical and experimental observations furnish strong evidence, and in some cases absolute proof, that certain transmissible human and animal diseases of unknown etiology are not toxic, but infectious, that is, caused by living organisms, capable of proliferation and metabolic activities.

2. In the case of the human diseases of this group, knowledge is farthest advanced in regard to those that are communicable to animals—hydrophobia, vaccinia and smallpox—and experiments on human beings have shown that the cause of yellow fever occurs in the blood, passes through Berkefeld filters, the filtrate being bacteriologically sterile, according to present methods, and that infection occurs through the medium of mosquitoes (*Stegomyia fasciata*). The etiology of the other strictly human diseases—syphilis, measles, scarlet fever, chicken-pox, typhus fever—remains unknown.

3. Certain morphologic elements in the lesions of vaccinia and smallpox are regarded by some investigators of the highest standing as representing stages in the developmental cycles of protozoa. The causative agents of these diseases do not pass through bacteria-proof filters.

4. The virus of many transmissible animal diseases (foot and mouth disease, peripneumonia, rinderpest, sheep-pox, chicken typhus, horse sickness, epithelioma contagiosum of fowls) passes through various filters ordinarily regarded as impermeable to the smallest known bacteria, the filtrates being virulent, though giving no sign of containing visible corpuscular elements.

5. Whether these invisible, and except in peripneumonia, uncultivable viruses are all ultramicroscopic in size, or invisible also for other reasons has not been settled definitely, but there is much in favor of the view that they are ultramicroscopic in size.

6. Further progress in this field may be expected from the application of methods recently introduced by physicists in order to furnish ocular demonstration of the existence of particles too small to be seen directly.

Elevation of the Larynx for Relief of Neuralgia.—Naegeli announces that he has frequently caused almost immediate cessation of cephalalgia and facial neuralgia, as well as forms of long-continued odontalgia, by simply elevating the larynx, holding it well upward for sixty or seventy seconds. This frequently requires to be repeated several times, but quite as frequently one single attempt will prove successful.—*Med. Times.*

TRIGEMINAL NEURALGIA TREATED BY INTRANEURAL INJECTIONS OF OSMIC ACID.

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

June 8, 1903, Mr. A. L. C., age 76 years, retired farmer, presented himself to me for treatment of a long-standing facial neuralgia. He gave the following history:

For thirteen years has suffered from neuralgic pains in right side of face, but they were not very severe or constant until four years ago. At that time he had a severe attack, which he thought was caused by a diseased upper cuspid tooth on right side. The tooth was removed about two months after the onset, and for the six weeks following he was relieved. Pain then recurred and was severe and persistent. Two years ago he had an operation performed on the right superior maxilla, the exact nature of which he does not know. He was free from pain for four months after the operation, but at the end of that time it returned, and has been present, at intervals, ever since. The pain is of severe shooting character, beginning at right ala nasi and radiating toward cheek. He also has some pain in the forehead, just above the right eyebrow, the pain radiating toward temple. General health has been fair for a man of his years.

Previous History.—"Ague," "bilious fever," etc., years ago. Used to smoke and drink moderately. Family history is negative.

Examination shows an old man of rather poor nourishment; lungs negative; heart negative; arteries sclerotic. Urinary examination negative. Slight tenderness over supraorbital and infraorbital divisions of fifth nerve at their foramina of exit. No areas of hyperesthesia or anesthesia and no evidences of tumor or inflammatory processes along the course of either nerve.

In considering the proper treatment to employ in this case, I was at first somewhat undecided. The superficial divisions, excisions or evulsions of the affected nerves at their foramina of exit would give the patient only very temporary relief, lasting, in all probability, only a few weeks or months. The excision of the nerve trunks external to the cranial foramina would have been a formidable operation, considering the poor physical condition of the patient, and would, I think, have given little better ultimate results. The recurrence would have been longer delayed, but just as certain as after the superficial operations. The intracranial division of the superior and inferior maxillary divisions with gutta-percha intervention to prevent re-establishment of nerve trunks (Abbe) was not applicable here, as it was the ophthalmic division that was most affected. The same objection would hold good with reference to Mayo's method of periosteal denudation of the bony margins of the foramina to secure bony occlusion of canal. Excision of the gasserian ganglion or resection of the sensory root within the cranium, was clearly contraindicated on account of the patient's age, the sclerotic condition of the arteries and his poor state of nutrition. An operation which is attended by a mortality of from 10 to 20 per cent. in robust patients is not to be thought of in a man 76 years of age, whose resistance is at a minimum.

Something, however, had to be done, so I decided to try the intraneural injection of osmic acid solution, as recommended by Mr. W. H. Bennett in the London *Lancet*, Nov. 4, 1899. In his paper, Bennett reports ten cases treated by this method, with most gratifying results in all. Eight of these cases were typical spasmodic tic, in one of which Meckel's ganglion had been previously removed and the inferior division resected at the base. In spite of these operations, the pain re-

curred in the buccinator muscle and was intolerable. Of the other two cases, one was a painful amputation-stump and the other a neuroma of the median nerve just above the wrist, following a division of the nerve by a piece of glass eight years previous. Without going into the reports of these cases minutely, suffice it to say that the results were all that could be desired and permanent up to the time the article was written.

The technic of the operation, as given by Bennett, and which I followed, is: The nerve is exposed through a small incision about a half-inch in length, directly over its foramen of exit, the line of incision being horizontal and parallel with the eyebrow, in the case of the supra-orbital branch, and with the normal creases of the face in the infraorbital and mental branches. The nerve is elevated by means of a blunt hook, and from five to ten minims of a fresh 1.5 per cent. solution of osmic acid injected directly into its substance. An ordinary hypodermic syringe and fine needle are used, and the solution injected in several different places, to be sure that every fiber is reached. After this is accomplished, a small amount of the solution is injected between the nerve and its sheath in the bony canal. During the procedure, a small pledget of cotton is held around the needle to absorb the excess of solution which regurgitates and to protect the skin. Wherever the solution comes in contact with the blood or soft tissues in the wound, an immediate blackening results, due to the formation of the hydroxid of osmium. The local action of the osmic acid on the terminal nerve filaments exposed in the wound is probably beneficial, so a small amount of it should be allowed to come in contact with them. After the injection is completed, the incision is closed with horse-hair or catgut suture; primary union follows, and healing is not interfered with by the action of the acid on the tissues.

My case was operated on June 11, 1903, under ether anesthesia. Local anesthesia should be used for this operation in the majority of cases. Bennett's technic was followed to the letter, and all three nerves, supraorbital, infraorbital and mental, injected. The operation lasted only about twenty-five minutes, and the patient came out of the anesthetic in excellent condition; pulse 66, temperature 99.6 F. He was put immediately in a semi-sitting position, as practically all of our patients are after operation, and the administration of fluids commenced as soon as he was awake.

In the afternoon his temperature was 99.8 F., and pulse 64. His pain had entirely disappeared. June 12, p. m., temperature 100, pulse 70; June 13, p. m., temperature 99.8, pulse 62; June 14, temperature and pulse normal; sat up in chair. After this temperature remained normal, he was up and around every day, and the sutures were removed June 17. Wounds healed by primary union. Patient discharged from hospital, with pain entirely gone, June 20. In a late report received from this patient July 21, he states that there has been no recurrence of the pain and that he feels perfectly well.

The modus operandi of this procedure is at the present time not definitely understood. The acid probably acts in one of two ways, or possibly in both: first, by producing a degeneration of the nerve on the proximal side of the injection, toward the ganglion; or, second, by causing a local destruction of the nerve and its terminal filaments. The former seems to me the more likely explanation of the two, first, because the pain does not usually subside completely immediately after the operation, as it does when the peripheral nerves are divided or resected, and as it would if the osmic acid produced only a local destructive effect. Instead, it subsides slowly and gradually, the patient, as a rule, not being entirely free from it for a week or ten days following operation. Second, the relief from pain is permanent, which is not the case after peripheral resection. In one of Bennett's cases there was a recurrence of the neuralgia, but not in the areas supplied by the nerves which he had previously injected. It was located in an entirely different area and yielded promptly to another injection of osmic acid.

Bennett, in his paper, does not describe the changes which take place in the nerves after injection, nor does he give his views as to the modus operandi of the treatment. I am now conducting a number of experiments on dogs, which, when completed, I hope, will throw some light on the subject.

The physician's post-graduate education comes from patients, from books and journals and from societies, which should be supplemented every five or six years by a return to a post-graduate school to get rid of an almost inevitable slovenliness in methods of work.—Osler.

The Obstetrician's Fee.—So long as the practitioner is so poorly paid for the valuable services he renders a woman at the time of her confinement, the woman will be neglected, and much that could be prevented will constantly happen. The average fee for obstetrical service in small towns and villages is $10, this service including attendance at the confinement and one visit during the puerperium. An extra charge is sometimes made for the application of forceps when urgently needed. The patient is not seen during her pregnancy, and in majority of cases not reporting for treatment or counsel until the call is made to the labor. The laborer is truly worthy of his hire, and if ever responsible service was rendered, it is during pregnancy, confinement and puerperium. The average workingman, on wages of $6 a week, can easily afford to lay aside $3 a month during his wife's pregnancy for the payment of the physician. When service is rendered, $25 is a very small fee for the work that *should* be done for a woman during her pregnancy, confinement and puerperium. The responsibility incurred, the care of two lives, etc., are as great as those of the surgeon in a celiotomy, and the fees should be commensurate. The profession is at fault, and with some unanimity of action the fees for obstetrical service could and should be raised.—*Louisville Monthly Journal of Medicine and Surgery.*

Eye Symptoms in Tabes.—During four and one-half years in Uhthoff's ophthalmologic clinic at Breslau, Mann found 165 cases of certain tabes and 200 with one or more suspicious symptoms. In the 165 certain cases the pupil reflex was normal in only one instance. Its absence, therefore, is a more frequent symptom in tabes than even the absence of the knee jerk. About 78.8 per cent. were in the early stages of the affection. Tabes was evident in 67.6 per cent. of the 136 cases during the same period in which the pupil reflex was absent, and general paralysis in an additional 8.8 per cent., while syphilis, with or without cerebral symptoms, was unmistakable in 8.1 per cent. The value of the ocular symptoms in tabes is that they may be evident long before any other manifestations appear. Syphilitic antecedents enhance the probability, but even without these the probabilities are three-fourths in favor of tabes. The pupils were unequal in one patient, an old syphilitic, who complained of slight disturbances in micturition, the legs a trifle anesthetic, the light reflex normal. A year later not a trace of any of these symptoms could be detected, and the man was apparently well, but when examined again, four years afterward, unmistakable signs of tabes had developed, showing that the unequal pupils five years before had been the initial symptom of the affection. Atrophy of the optic nerve was noted in 33.3 per cent. of the 165 patients, and in 27.2 per cent. of these there was ataxia. Mann's article is published in the *Allg. Med. Ct.-Ztg.*, lxxi, p. 635.

KUSSMAUL'S AUTOBIOGRAPHY.

In 1899 appeared *"Jugenderinnerungen eines Alten arztes,"* in which the distinguished clinician, Professor Kussmaul, delighted his students and friends the world over with pictures of his early days in Heidelberg and of his *Wanderjahre* in other university towns. As an autobiography the work in many respects was unique. The style was charming and the sketches of his old teachers and of the stirring days of '48 proved so entertaining to the profession and the public that five editions were called for within four years. The volume ended with the story of his life as a country doctor in the Black Forest; then a desperate illness (acute paraplegia), gradual recovery, return to Heidelberg—and what seemed to the young doctor with a wife and two children a hopeles tragedy proved to be only the starting point in a career of singular brightness. One thing gave to the work an unusual attractiveness, it ended where biographies, particularly autobiographies, often begin—we saw only the struggles, trials and difficulties of the early years, there was no word of the distinguished teacher or much-sought-after consultant. Every reader felt that he would like another installment of such charming reminiscences.

Kussmaul died May 28, 1902, in his 80th year, suddenly, as he had hoped. Professor Czerny, the distinguished surgeon, has edited *"Aus meiner Docentenzeit"* in Heidelberg, in which he gives an account of his life as a young teacher. Before beginning work he went to Wurzburg to study pathology with Virchow and to take anatomic and chemic courses. A couple of months were spent at the asylum of Illenau, where he became interested in epilepsy, a subject on which he made his well-known researches in 1857, and on which, as we learn from the preface, he was preparing a monograph at the time of his death. An assistant physician was Gudden, who afterward become so well known; of his tragic death while in charge of the King of Bavaria, Kussmaul gives an interesting account. There seems to have been some difficulty in getting permission to teach at Heidelberg, and a most amusing description is given of his habilitation thesis, which pleased neither the faculty nor the authorities. He began to lecture on therapeutics in the winter of 1856-1857, and later on toxicology, psychiatry and legal medicine. Young teachers may read with profit what he says about the difficulties experienced in becoming facile of speech, and of the difference between *Zungenfertigheit,* which is congenital, and *Redefertigheit,* which is acquired. It took much trouble, time and practice before he became a fluent speaker, adopting finally the plan of a skeleton of headings from which the lecture was carefully elaborated beforehand. He quotes from an old friend two golden rules—to give your audience at appropriate places a brief rest, and to hold the hearers with your eyes.

Some of his early work is described, the studies in rigor mortis and his important contribution to the structural anomalies of the uterus. Perhaps the most interesting chapters are those describing the old and young naturalists and physicians of the university, and the social life in Heidelberg; of Kirchhoff, Bunsen and Helmholtz, a group of inspiring teachers hard to match in the early fifties, and of others less celebrated there are delightful reminiscences and anecdotes. One of the little touches from the hand of a master is the story of Johanna Kapp, the disturber of hearts of his student days. The concluding chapter gives an interesting account of the organization of the Association of German Naturalists and Physicians, and of the meetings at Bonn and Karlsruhe.

We regret that we do not see in Professor Czerny's introduction any notice of a continuation of this autobiography. In Erlangen, in Frieberg and in Strassburg Kussmaul took an important part in the development of scientific medicine and he reached a position of the very first rank among the physicians of Europe. But he was more than this—the qualities of heart and head were equal; he was a good as well as a great man.

THE CARNEGIE INSTITUTION AND MEDICAL RESEARCH.

Since the establishment of the above institution by Mr. Carnegie, speculation has been rife among medical men as to what provision, if any, would be made for investigation in the field of medicine. In a recent address, the president of the Carnegie Institution, Mr. Daniel C. Gilman, made very clear the policy to be pursued by the board of directors in this matter. After paying a tribute to the scientific workers who have so notably enriched medical knowledge in the recent past and expressing the conviction that medicine is at the present moment on the threshold of discoveries of the highest importance, Mr. Gilman stated that it was the purpose of the Carnegie Institution to confine its medical work to the study of the normal, and to leave the inquiry into the abnormal to the Rockefeller Institute for Medical Research.

As an example of the kind of problems the Carnegie Institution will attempt to solve, the speaker referred to the subject of nutrition, emphasized the desirability of an extension of our knowledge in that field, hinted that it was one in which very profitable work could now be undertaken and gave the impression that investigators of merit attempting to deal with problems bearing on it would receive liberal support from the board. A begin-

ning has already been made. The services of Dr. Gangee have been secured. This well-known physiologic chemist, having agreed to spend some time in preparing for the board a report in which he will offer an opinion as to the present status of the problems connected with nutrition, and point out the paths along which, in his judgment, research should proceed to yield the most important results in the immediate future.

Nothing was said by Mr. Gilman in the address referred to regarding problems in human anatomy, but there can be little doubt if research in physiology is to be subsidized, that the study of anatomic problems will also be supported. Besides, the liberality of the Carnegie Institution, with regard to the Marine Biologic Laboratory at Wood's Hole, is sufficient proof of the interest of the board in the problems of general morphology. We can be sure, therefore, that the great significance of the unsolved questions in human morphology will not be overlooked. Anatomists tell us that nowhere perhaps could money be better expended than in illuminating some of the obscure regions in human histology, embryology and neurology.

The relegation of the whole domain of pathology to the Rockefeller Institute throws a great responsibility on the latter institution. It is a responsibility, however, which the founder of the institute and its board of directors seems willing, as far as in them lies, to assume. Hitherto the medical profession has had to depend in large part on its own unaided and unendowed efforts when it wished to advance medical knowledge. It is a matter for congratulation that the industry and self-sacrifice of the profession are to be supplemented from now on by the activities of two great research foundations, one directing its attention to the phenomena of the normal human body, the other to the phenomena presented by the human body in disease.

EDISON AND X-RAY INJURIES.

At this somewhat late day, Mr. Edison and, through him, the newspapers have all of a sudden discovered that *x*-rays can cause injuries, and, like many other belated discoveries, the topic is now one of lively interest in the daily press. According to the various newspaper reports, Mr. Edison's injuries are interesting. His left eye is out of focus, his digestion is upset and lumps have formed all through the region of his stomach. He knows it is the result of the *x*-rays, because he held the tube close to his stomach when he was working with *x*-rays five or six years ago. The disease from which he is suffering is of a most mysterious character, and no doctor is able to tell him anything about it; and he ought to have been able to find out, for among the many specialists he has consulted there is one man who has dissected more than four thousand bodies, and if a man who has made four thousand dissections can not tell you what is the cause of lumps in your stomach, who can?

The injuries to Mr. Edison's assistants are of a much more tangible character. Without any doubt they have had *x*-ray burns, but there is nothing to indicate that the burns are not of the ordinary character of other *x*-ray burns. It is probable that his assistant, whose arm had to be amputated, is one of the cases which have been recently mentioned in the literature of epithelioma developing in an *x*-ray dermatitis of long standing. From the character of chronic *x*-ray burns the possibility of epitheliomata developing in such injuries has been pointed out by Pusey, and cases of this sort have been reported by Allen and White, and others.

If we are to believe the newspapers, Mr. Edison does not stop at recounting his strange experience, but readily offers an explanation for it, namely, that the condition is due to the action of the rays on the phagocytes; that the rays paralyze the active phagocytes without actually destroying them—all of which is somewhat bewildering. In view of the careful studies of *x*-ray injuries that have been made by Scholtz, Grouven, Gassmann, Pusey and others, which show very definitely the changes that occur in tissues under the influence of *x*-rays, it would seem that his histologic discoveries are not of serious interest. He has, as far as can be judged by the newspaper reports, found nothing that has not been found before, and offered no explanation that is of any value. He is rehashing in the daily press facts that had been learned by physicians through sad experience seven years ago. The whole thing seems to be a good deal like the promised storage batteries, a useful vehicle for publicity when propelled by the power of a widely known name.

PRACTICAL VALUE OF BACTERIOLOGIC EXAMINATION OF THE BLOOD.

That the bacteriologic examination of the blood in cases of infectious disease has been of scientific value and has modified our conception of many of these diseases is well known. That this method of examination is also of practical clinical value is clearly set forth in an article by Hektoen,[1] in which the results of his own work and those of others are considered from the point of view of their practical application in medicine.

The technic is simply that of obtaining with scrupulous asepsis a few cubic centimeters of blood and immediately inoculating media, e. g., bouillon, with the same, placing in the incubator and identifying by ordinary bacteriologic methods the organisms that may appear. A glass syringe is used, and a vein at the elbow commonly selected. The operation is almost painless. Ordinary bacteriologic training is a prerequisite to the successful application of this method and fairly complete laboratory facilities are essential, but no unusual skill is required.

The results already obtained are seen in the septicemias. Etiologic diagnosis is now possible. This is an absolute essential before specific serum therapy can be

1. Hektoen: The Practical and Scientific Value of Bacteriologic Examination of the Blood During Life. Illinois Medical Journal, July, 1903.

applied. And only by a careful study of many cases with bacteriologic examination of the blood to control the diagnosis can clear clinical pictures of blood infections be obtained. Already something has been accomplished in this line, largely through the bacteriologic study of the blood, as may be seen from reading the recent monograph by Lenhartz.[2] Our views as to prognosis in the septicemias must be somewhat modified. As shown by others and as Hektoen has found in his own work in scarlet fever, the presence of streptococci in the blood does not necessarily mean death.

The results in pneumonia are of value as the pneumococcus may be found in probably all cases. The work of Rosenow with the pneumococcus has been recently noticed in these columns. But of much greater value from the diagnostic point of view is the ability by bacteriologic examination of the blood to recognize typhoid fever before the spots, splenic enlargement, peculiar temperature, curve or agglutination reaction are present. No early physical signs, as in pneumonia, enable typhoid to be recognized before several days of fever have elapsed. By this means, however, it is recognized, and with certainty, often as early as the third day of the fever. And the only positive means of differentiating between the paratyphoid and true typhoid is offered in blood examination.

Physicians too often get the impression that research is wholly and purely of theoretical value. While there can be no higher class of investigation than that carried on for the sole purpose of discovering scientific truth, it is well for us to have the fact called to our attention as in this paper, that from all the enormous mass of laboratory research there is sure to result sooner or later knowledge that can be placed before the physician with the assurance that it is a help in his efforts to recognize and cure disease.

OZONE AND WATER PURIFICATION.

It has long been known that ozone is a highly effective germicide, but the great cost of production and other difficulties have proved for many years a barrier to its use on any large scale. Within the last four years new and interesting experiments on the purification of water by impregnation with air containing a high per cent. of ozone have been conducted in various parts of Germany. These have been carried out with a form of apparatus designed by the famous manufacturing firm of Siemens and Halske. The experiments have been followed bacteriologically by Ohlmüller and Prall,[1] by Schüder and Proskauer,[2] and others. The results have shown that the germs of Asiatic cholera, of typhoid fever and of dysentery can be surely destroyed in the ozone generating appliances under ordinary practical conditions of operation. Small ozone plants have been installed in connection with the water-works at Paderborn and at Schierstein, near Wiesbaden, and are said by Proskauer and Schüder to yield a water very low in bacteria, the number in the raw water being sometimes reduced from 20,000-30,000 to only 8-10. The ozone is generated by electricity, and the amount introduced into the water is so adjusted on the basis of carefully controlled experiments as to afford a maximum of operative efficiency at a minimum of ozone content. The results as stated certainly seem to indicate that for dealing with certain waters and with small town supplies the method is worthy of further investigation.

The item of expense, however, even at its present relatively low figure, is still far from reassuring. According to the published statements,[3] the cost of water purification by the ozone process has not been reduced below about $18 per million gallons, whereas the total cost of sand filtration, a tried and efficient method of water purification, is estimated, including interest and depreciation, at from $7 to $9 per million gallons. It is evident that some experimentation under American conditions will be needed before the treatment of water supplies by ozone can be indiscriminately advocated as applicable to the larger public supplies of this country.

MEDICAL CONTINGENT FEES.

In a damage case recently tried in a Colorado court it was brought out in the testimony that the attending physicians testifying for the plaintiff had a contract to accept as their fee a certain percentage of the award in case the suit was successful. The attorneys for the defendant corporation, naturally, made the most of this admission, holding that it was an agreement contrary to good policy and morals, while the physicians, on the other hand, claimed that the transaction was an innocent one; that, as the injured person was poor, she was allowed to contract to pay her bill in this way. There is something to be said on this side, and it does not necessarily follow that the chance of a contingent fee should influence the testimony as to the fact of the physicians. Indeed, we believe it would not, but the whole business has a dubious appearance, and the average layman is apt to put on it the very worst construction. The physician who makes such a contract is put before the public as a promoter of litigation, a sort of medical champertor, by the opposing parties if it comes before the jury, and must suffer all the prejudice that can be thus aroused. While contingent fees are undoubtedly common enough with the legal profession, they certainly are not in the medical, and it would be more in accord with the spirit of the principles of medical ethics to take the chances of losing a fee rather than those of subjecting oneself to the possible interpretations of the other course. There are occasions when one may be too business-like, and this is one of them.

MEDICAL JURIES.

It has been suggested that in criminal cases in which questions of mental sanity or other medical questions

are involved there should be a jury of physicians. Thus can be avoided, it is to be inferred, the scandal of conflicting "expert" testimony (so-called), which is so often used, it is claimed, to befog the jury and embarrass justice. It is assumed that a medical jury would be able to properly interpret the evidence and reach a correct conclusion where an ordinary jury of laymen would fail. This seems plausible, but will hardly bear examination. The plan would fail for the same reason that our present much-criticised usage of expert testimony fails; because it is based on the presumption that every physician is necessarily an expert in every branch of his profession. It is discrediting no one to affirm that an eminent surgeon may be almost as incompetent as a layman in questions of psychiatry, and vice versa, though there may be many individual exceptions to the rule. Medicine is a broad subject, and one who contracts to cover the whole field as an expert will find that he has undertaken to master a pretty considerable fragment of omniscience. Yet there are many who thoughtlessly, we believe, will offer opinions or testimony on subjects that they can not have adequately considered or studied and in which they have had no special experience. This, far more than any intentional dishonesty, has brought expert testimony into disrepute. The assumption that an average panel of medical jurymen would insure a correct verdict in cases where medical points are involved is by no means justified. They would be better able than intelligent laymen to estimate the value of certain kinds of evidence, but there would still be infinite chances for error. The proposed plan would certainly fail to right all the wrongs of the present methods, the real remedy for which is in a more discriminating estimation of what is to be accepted as expert testimony. The advantages of the plan could never counterweigh the reasons of public policy that have practically exempted physicians from jury duty; and we should protest against the imposition of such on a profession that in numberless other ways does more than any other for the public weal. This is saying nothing of the improbability of counsel ever accepting those who are so prominently wanting in the prime requisite of unintelligence.

THE REPORTED "CURE FOR LOCKJAW."

During the past week the papers have circulated reports concerning the discovery of another "wonderful cure," this time in the way of a cure for tetanus. The facts in regard to the matter, as we understand them, are as follows: Several months ago Dr. S. A. Matthews described before the Medical Club of the University of Chicago his experiments with "cell cathartics," as he terms them. His solution is a mixture of sodium chlorid, sodium sulphate, sodium citrate and calcium chlorid, which, when injected into the veins directly, seems to have much the same effect that similar solutions have in the body, causing fluids to leave the cells or interstices in the body, at least there is a great increase in the amount of fluid excreted by the kidneys of experimental animals, which is much in excess of the amount of fluid injected. According to Matthews' experiments, such intravenous infusion will rapidly wash out any toxic substance that may have been introduced, such as morphin, and also bacterial toxins. He performed a series of experiments on rabbits, which seemed to indicate that this solution in these animals was able to remove the toxin even after it had combined with the nervous system and produced symptoms, and to save the lives of many of the animals when the controls died. These results, with certain conclusions, were reported at the meeting that we have mentioned, but, so far as we have been able to learn, have not been published. Attention is called to the fact that Dr. S. A. Matthews is not to be confused with Prof. A. P. Matthews, who is assistant professor of physiologic chemistry at the University of Chicago, the newspaper accounts having given the title of the latter to the former. The name of Dr. S. A. Matthews does not appear in the circular of the university of April, 1903, as connected with the institution, although we understand that he is giving a course in pharmacology during the summer session. This case, which has been reported by the newspapers as cured by the saline cartharsis, is said to have had a long period of incubation and to have started out as a case of chronic tetanus, but after a rather protracted course had seemed to be growing worse, when this treatment was begun. The infusions were repeated frequently, and the boy has recovered. In other words, there is a single case of chronic tetanus that has recovered under this particular form of treatment. It seems much like the recent furor concerning the intravenous injection of formaldehyd in septicemia, but with this difference: formalin intravenous injection was opposed by experimental study previous to the public report, and also by clinical experience, the use of any substance that will increase renal elimination in tetanus is indicated in tetanus, and Dr. Matthews seems to have applied the results of laboratory experiments to a human case. An objectionable feature of the case is the prompt appearance of full accounts of the case in the daily press. Who is responsible for this we do not know, but the natural and proper result is to cause a profound and general scepticism among all physicians. However, such publicity does not necessarily brand the work as unscientific, and we trust that Dr. Matthews may continue his work, and wish him success in some more acute cases. Until such cases have been reported through professional avenues we recommend that the matter be held by the profession *sub judice*.

Medical News.

ILLINOIS.

Gift to Hospital.—Abram Brokaw, Bloomington, has made a donation of $30,000 to the Brokaw Hospital in that city.

Illinois Water To Be Analyzed.—The State Board of Health is about to make a systematic investigation of the water supplies of the different cities of the state for the purpose of discovering whether the water is likely to be prejudicial to health. The water will be collected under the direct supervision of the board, and a careful chemical and bacteriologic analysis will be made of each sample under the direction of Professor John H. Long of the Northwestern University, Chicago.

State Charities.—The quarterly report of the State Board of Charities shows a surplus of $192,294.11. The average number in the state charitable institutions was 11,165. The total per capita cost for maintenance was $40.27 gross, or $37.79 net. The following is the net per capita cost for the quarter in all the institutions: Elgin Insane Hospital, $41.79;

Kankakee Insane Hospital, $36.96; Jacksonville Insane Hospital, $37.65; Anna Insane Hospital, $33.44; Watertown Insane Hospital, $30.91; Asylum for Incurable Insane, $41.13; Asylum for Insane Criminals, $51.17; School for the Deaf, $52.61; School for the Blind, $51.53; Feeble-minded Asylum, $33.98; Soldiers' and Sailors' Home, $29.15; Soldiers' Orphans' Home, $51.04; Soldiers' Widows' Home, $49.91; Eye and Ear Infirmary, $56.97, and Training School for Girls, $42.30.

Chicago.

Will Enlarge Hospital.—Alexian Brothers' Hospital has purchased a plat of land adjacent to the hospital, 485 by 125 feet, for $10,000.

Personal.—Dr. G. Le Roy Brown, has returned from Europe. ——Dr. Ernst Riebel has been appointed an associate member of the County Hospital surgical staff.

General Hospitals Require No Frontage Consent.—Acting Corporation Counsel Fyffe has given an opinion to the effect that general hospitals are not required to secure the frontage consents of residents in the same block in order to build. The officials of Augustana Hospital applied for a building permit for an addition. Hospitals for the insane, inebriates and the treatment of contagious diseases require frontage consents.

Impure Milk.—Out of 760 samples of milk and cream analyzed in the health department laboratory during the week ended August 15, 60 were found below grade. Among these 760 samples from all sources there were 112 taken at the trains—before the milk had come into the possession of the city dealer. Out of these 112 samples four were found below the standard of butter fat and 40 below the standard of total solids.

MARYLAND.

Baltimore.

Personal.—Dr. A. D. McConachie is at Lucerne, Switzerland. ——Dr. Walton Bolgiano is at Asbury Park.——Dr. T. A. Ashby is in Virginia.——Dr. J. B. Crenshaw has returned after nearly a year spent in study at Berlin.——Dr. Samuel Johnston is at Narragansett Pier.

Deaths of the Week.—During the week ended August 15 there were 190 deaths, an annual death-rate of 17.66 per 1,000. This is much below that of the corresponding week of the three previous years. Thirty-five of the deaths were from diarrhea; 6 from typhoid fever, and 3 from dysentery.

Prevalent Diseases.—Scarlet fever and diphtheria are very prevalent, especially in East Baltimore. There were 115 deaths from the former in July and 94 from the latter. The health department will make every effort to prevent their spread on the opening of the public schools in September.

NEW YORK.

Incubator at Coney Island.—The infant incubator which was so successful at the Pan-American Exposition is now stationed at Luna Park, Coney Island. At a recent visit, there were fifteen premature-born children alive and thriving in the hospital.

Influenza.—The State Board of Health has issued a bulletin in which is reviewed the reports on influenza for the first half of the present year. It is stated that more deaths are ascribed to influenza in the first year of life than in the next twenty years, and that only one-fourth of the deaths occurred before the age of 50. The greatest number of deaths occurred between the ages of 70 and 80, and the disease was most prevalent in December, January, February and March. It is to be noted that at all ages, with the exception of the first year of life, more females than males succumb to the disease.

Buffalo.

Personal.—Dr. Grosvenor Trowbridge has returned from a visit to Cayuga Lake.——Dr. Julius Ullman has returned from Atlantic City and New York.——Dr. Roswell Park has taken a trip up the lakes.——Health Commissioner Green is spending his vacation fishing in Northern Canada.

Substitute Internes.—Recently there has been a great deal of agitation in one of the daily papers concerning young internes in the Buffalo hospitals. In one or two instances the medical internes were found to be senior students. It is often customary to have students substitute for internes who are on short vacations. They, however, never have the responsibility of examining or treating cases, but attend to such duties as are required in the laboratory, making urinalyses and blood examinations, etc.

July Statistics.—The monthly report of the Department of Health for July shows an annual death-rate of 16.2 per 1,000. The principal causes of death were as follows: Consumption, 33; cholera infantum, 40; pertussis, 7; typhoid fever, 10; debility, 16; marasmus, 16; cancer, 31; apoplexy, 19; meningitis, 14; tetanus, 1; valvular heart disease, 19; pneumonia, 22; appendicitis, 8; cirrhosis of liver, 4; gastroenteritis, 25; nephritis, 15; diabetes, 8, and violence 43. The total deaths were 513, as compared to 413 for July, 1902.

Milk Waterers Prosecuted.—Twenty-one milk dealers who water milk are being prosecuted by the commissioner of agriculture. The department originates its own cases; agents from time to time unexpectedly examine the milk in peddlers' wagons. If it falls below the test a chemical analysis is made, and if this shows the milk contains more water than is natural suit against the milkman is begun. These suits are tried in the Supreme Court, and the penalty imposed by the law is $50 to $100 for the first offense and from $100 to $200 for the second offense.

New York City.

New Hospital and Dispensary.—A new dispensary and hospital has been established at 347 East 116th street, having accommodations for 20 patients. The following constitute the visiting staff: Drs. Salo Cohn, Reuben Cronson, I. Goldstein, Herman Jarecky, Robert Kunitzer, I. Levin, Louis Lichtschein, J. Mark and Leopold Marcus.

The New Bellevue Hospital.—Negotiations have been going on for some time looking to the purchase of land adjoining the present Bellevue Hospital in order to provide a site for the new hospital building. It is now stated that all obstacles have been removed and that it is expected to begin the erection of the buildings early in the fall. When acquired the total area of grounds is represented by all that tract of land lying between Twenty-sixth and Twenty-ninth streets, First avenue and the East River.

The Infant Hospital of New York was recently visited and found to be most complete in all its requirements. Of especial interest was the steam room for infants suffering from croup or pneumonia. The entire bed is placed in this room, while the nurse watches the patient through a glass partition. It is an excellent suggestion for use in pneumonia and influenza, as well as nephritis of adults. In the laboratory work was being carried out on the bacteriology of summer diarrheas with reference to the Shiga bacillus as the causative factor. There were some summer diarrhea cases in the hospital, but scarcely any of the severer cholera infantum variety on account of the unseasonably cool weather.

Barber-Shop Sanitation.—Although steps have been taken in the past to secure certain sanitary reforms in barber shops, such regulations have been chiefly honored in the breach. The Board of Health now gives warning that after September 1 the new rules will be rigidly enforced. These rules provide that the barber shall wash his hands with soap and hot water before attending any person; that the use of powder puffs shall be abolished; that a towel shall not be used for more than one person without being washed; that sponges shall no longer be used; that mugs, combs, razors, clippers and scissors must be rinsed in boiling water or in some germicide each time after use; that alum or other astringents shall not be used except in the form of powder, and that a copy of the regulations must be conspicuously posted in each shop.

GENERAL.

Committee on Public Health.—Dr. Heman Spalding of the Department of Health of Chicago has been appointed chairman of the Committee on Public Health of the American Medical Association.

All Medical Schools Now Have a Four-Year Course.—It is encouraging to note that while two years ago we reported three medical colleges as requiring only three years' course for a degree, last year there was only one three years' school left, and this year there is none.

Dallas Medical College.—Belated statistics from this Texas school, mentioned in the Educational Number, show that it has a faculty of 30; fees: matriculation $5, annual tuition $75, graduation $25 extra; the enrolment 1902-3 was 213, graduates 30. The next session opens Oct. 1, 1903.

FOREIGN.

International Congress of School Hygiene.—Such prominent men as Baginsky, Hoffa, Eulenburg, Cohn and Hueppe are

interesting themselves in the first international congress for school hygiene. It is planned for next spring at Nuremberg.

"Archives Internationales de Chirurgie."—Professor Ch. Willems of Ghent has issued the first number of this new periodical. The articles are published in the mother tongue of the writer, followed by a summary in four other languages, English, French, German, Italian or Spanish.

Touring Scholarships.—The Touring Club of France publishes in the last *Presse Médicale* a notice to the effect that two medical students, with high honors in their classes, will be given a free bicycle trip with a party touring through the Alps, down to the Mediterranean and home by the Rhone.

The Discoverers of Radium.—Last month the wife of Dr. P. Curie, professor of physics and industrial chemistry at the Paris Ecole Municipale, presented her thesis at the Sorbonne for the degree of doctor ès sciences. Her subject was "Radium," whose properties were discovered by the collaborated research on uranium of this couple.

French Congress of Surgery.—The sixteenth annual meeting of the French Association de Chirurgie will be held at Paris, October 19 to 24, as previously announced. Prof. C. Périer will preside, and Duret, Lille, will deliver the address on "Tumors of the Brain," and Dr. Hartmann on "Exclusion of the Intestine," the two subjects appointed for discussion.

Medal for Cornil.—Professor Cornil of Paris reaches the time limit of his service at the Paris Hotel Dieu this year. He is to be presented by his friends with a medal commemorating his work in the history of pathology and bacteriology. A bronze copy of the medal will be sent to those who subscribe $5, to be sent to M. Alcan, 108 boulevard Saint-Germain, Paris.

Pathogenic Agent of Rabies.—Dr. A. Negri, Golgi's assistant at Pavia, announced last March the discovery of the specific micro-organism of rabies. He now states that he has examined more than 100 dogs with natural or laboratory rabies, and has never failed to find the specific micro-organism in the nerve centers. On the other hand, he has never found it in other dogs.

French Congress of Alienists and Neurologists.—The thirteenth congress convened at Brussels, August 1, and discussed the questions appointed for the order of the day with addresses by Claus, Antwerp, on the first theme, "Catatonia and Stupor"; by Klippel, Paris, on the second, "Histology of General Paralysis," and by Trenel, Saint-Yon, on the third, "Treatment of Agitation and Insomnia in Mental and Nervous Disease."

Grassi's Studies of Goiter and Cretinism.—When Grassi undertook the study of the etiology of malaria he went to reside in a malaria-infested district, where he spent months in collecting and examining mosquitoes. He has now entered on similar research in regard to the etiology of goiter and has taken up his residence in a small village in a valley on the Italian slope of the Alps, Cedrasco, in the Veltlin district. Our readers will remember that one of the large prizes was conferred on him at the Madrid congress.

Prize Offered for Pamphlet on Advantages of Bathing.—The German Public Bath Association offers three prizes of $25, $37 and $50 for the best pamphlets or circulars portraying the advantages of systematic bathing. The one winning the prize will be distributed and placarded for the purpose of educating the masses and also to arouse interest to provide better facilities for public baths. Competing articles should be sent to the office of the association, Karlstr. 19, Berlin N.W., VI., where further particulars may be learned on application.

German Medical Exhibit at the St. Louis Exposition.—The Germans are planning to make an elaborate exhibit of everything connected with medical instruction, especially in respect to diagnostics and therapeutics. Professor v. Bergmann is in charge of the matter, assisted by a committee, which includes Kutner, Kraus, Mikulicz, Orth, Rubner, Waldeyer, Wassermann and others, nearly all of Berlin. A circular inviting co-operation is to be sent forthwith to all the prominent institutes and firms throughout Germany.

Cause of the Pope's Death.—The diagnosis of the physicians, "catarrhal inflammation of the lung, with a hemorrhagic pleuritis," was confirmed by the autopsy. Our Italian exchanges state that with the exception of this one lung and pleura, all the organs were found normal, except for a small patch of atheroma on the aorta. The number of "sovereign remedies," amulets, charms and similar articles, sent to the physicians and to the Vatican from all parts of the world, to be used on the illustrious patient, is almost beyond belief.

Silver Jubilee of Professor Pawlow.—A committee has been formed in Russia to get up a "Festschrift," to contain works on physiology and pharmacology, to be presented in February, 1904, to Prof. J. P. Pawlow on the occasion of the twenty-fifth anniversary of his entering on his scientific career. Professor Ssimanowski has the matter in charge. At the same time a fund will be endowed in Pawlow's name for a prize to be awarded for important works on physiology. Contributions for the endowment fund and for the "Festschrift" may be sent to Dr. Hanicke, Lopukhinskaya No. 12, St. Petersburg.

Circular Warning Against Venereal Diseases.—The German Preventive Association has empowered professors Erb, Jadassohn and Fraenkel to write the text for a warning circular to be sent to all the physicians of Germany for free distribution among their patients. It will point out the dangers of infection, the necessity of early and thorough treatment and the precautions to avoid infecting others. The association also recently voted to petition the government for more stringent measures against charlatans, citing particulars in regard to the harm done by their practices in the domain of venereal disease.

Lister Institute of Preventive Medicine.—A movement was started in London in 1896, the centenary year of Jenner's experiments in proof of the efficacy of vaccination, to perpetuate his name by some suitable memorial. It was finally decided to change the name of the British Institute for Preventive Medicine by substituting the word "Jenner" for "British." It was found, however, that a commercial firm had a prior claim to the name Jenner Institute, and the complications arising were so many and varied that it was finally decided to give up the name. Instead of again assuming the old name, another man was honored and his name perpetuated by calling it the Lister Institute of Preventive Medicine. Jenner's name is also to be perpetuated, as there has been endowed a Jenner memorial studentship in connection with the Lister Institute.

The Approaching International Congress of Ophthalmology.—Elaborate preparations are being made for this congress, which will be held at Lucerne, Switzerland, Sept. 19 to 21, 1904. Only one official subject has been announced for discussion: "The Question of Indemnity as Regards the Value of an Eye, Lost or Injured." Addresses on this subject have been requested from Axenfeld of Freiburg, Sulzer of Paris and Würdemann of Milwaukee. The committee of organization includes Snellen of Utrecht, Barde of Geneva, Dufour of Lausanne, Haab of Zurich, Pflüger of Berne, Landolt of Paris and Mellinger of Basle. The latter is the treasurer, and will send the admittance card on receipt of the fee of $5. Further particulars may be learned from Dr. de Schweinitz, 1401 Locust street, Philadelphia, or Dr. Coote, Quebec, Canada, who have been appointed correspondents for this country. Communications destined for the congress, if received before May 1, 1904, will be published and sent to each member of the congress with his admittance card. The reading out of the papers may thus be dispensed with, and the author will merely state his conclusions, thus giving time for discussions in the mornings and demonstrations in the afternoons. The committee are anxious to bring together at this congress all objects, old and new, relating to ophthalmology. They also plan an official banquet and numerous fêtes and excursions.

Panhellenic Medical Congress.—The second congress of Greek-speaking physicians and surgeons was held at Athens, May 17 to 23, as announced. A large number of communications on anatomy, physiology, etc., were presented, but most of the themes revolved around the study of malaria. Its relations to the circulatory and nervous systems were discussed, with addresses. Triantaphyllides of Batoum has noted 67 cases of cardiopathies in an experience with 12,000 malarial subjects. The endocardium was affected in 39, with lesions of the mitral valve in 23. In 16 the endocardium was ulcerated. In 26 cases the myocardium was affected; the pericardium in 3; the aorta in 1. Manoussos, Athens, regards malaria merely as a predisposing cause for heart affections, phlebitis, etc., but Coryllos, Patras, is dubious, and cited an instance in which a polyphlebitis developed in an old malarial subject, with fever, pains, tenderness and slight edema, all of which disappeared under treatment with the usual measures supplemented by constant use of quinin. Kanellis, Athens, stated that phlebitis frequently occurs consecutive to malaria, and that the latter may induce both functional and organic heart

trouble, although organic lesions are rare. He has observed cases of a malarial aortitis in patches, usually on the ascending aorta, also of malarial aneurism of the aorta, angina pectoris from constriction of the coronaries, and of Raynaud's disease. Maroudhis, Athens, called attention to the great value of lime for extermination of mosquitoes. One part of quicklime to 100 parts of water will kill the larvæ in the water in two and one-half to five hours if pulverized, and if thrown into the water in chunks the larvæ are all killed in twenty-four hours at farthest. The powdered lime forms a coating on the surface which has a supplementary insecticidal effect. Koumoulis announced that cholera germs on dry bank bills all die in less than an hour.

Fifth Brazilian Medical Congress.—This successful national congress was held at Rio de Janeiro, June 16 to 20. The communications were mainly on the subject of tropical diseases and allied topics. Great interest was aroused by the results of serum treatment of plague reported by Dr. Victor Godinho of San Paulo. He is accustomed to administer the anti-plague serum by the intravenous route and in amounts much larger than elsewhere ventured, even as much as 60, 80 or 100 gm. of the serum at once. The effect on the hyperpyrexia is remarkable. The temperature drops several degrees almost immediately. He exhibited a large number of curves showing the benefit derived from the serum treatment in this respect, which practically arrests the disease process. Serum treatment of snake bites was discussed by Dr. Vital Brazil, also of San Paulo, who described important experiences with specific serum prepared at the institute in his charge. It proved much more effective than the control tests with Calmette's anti-venom serum. The members of the congress were so impressed with his success in curing snake bites with this anti-ophidic serum, as he calls it, that a resolution was passed urging the state to appropriate the funds necessary to send him to Europe to compare and make known what Brazil has accomplished in this line. He reported 21 cases in which persons known to have been bitten by venomous snakes and treated with the serum recovered with slight, if any, clinical symptoms, while even a fraction of a milligram of the venom causes severe symptoms in animals. In three of the cases the symptoms developed with extreme rapidity and gravity, but all subsided after injection of 20 to 60 c.c. of the serum. Two hours had elapsed in one case and three in another. He makes three kinds of anti-venom serum, including one for rattlesnake bites. His article is published in full in the *Revista Medica de S. Paulo*, No. 2, 1902, and No. 13, 1903. The *Brazil Medico* is publishing a detailed account of the congress.

LONDON LETTER.

Plague in India.

Plague is becoming more widespread every year in India, and the government is confronted with a very serious problem. The great difficulties in applying measures to check the spread of the disease which are offered by the ignorance and religious prejudices of the natives have been before described in THE JOURNAL. The disease is now widespread over all the most densely populated parts of India excepting Eastern Bengal and Assam. In April last over 30,000 deaths per week were recorded. The nature of the problem to be faced by the government will be realized if it is remembered that in each district of 1,000,000 inhabitants there are four administrative and one medical European officer who are more than fully occupied without any extra plague work. Coercive measures prove futile and have led to wholesale concealment and flight of infected persons to previous uninfected places. Compulsory isolation, evacuation and disinfection, except in the first few cases in any locality, have been abandoned as useless. In their place facilities for voluntary inoculation, for disinfection of infected houses, and for voluntary evacuation are afforded. A huge scheme for the inoculation of 10,000,000 of people in the Punjab was wrecked by the lamentable mishap in November, 1902, by which 19 natives died from tetanus following the inoculation (THE JOURNAL, April 25, p. 1153). A most favorable start had been made, 200,000 natives had been inoculated in the first two weeks, with the aid of a large number of specially imported doctors. After the mishap the inoculations had to be suspended. Later they were resumed, but the harm done was irrevocable. It is indeed remarkable that 300,000 more were carried out. The results, so far, have been satisfactory: the proportion of deaths to cases among the inoculated was 25 per cent., among the uninoculated 60 per cent. The advantages of substituting voluntary for compulsory measures in Allahabad is shown by the following facts: When the disease was established compulsory measures were abandoned and the system was adopted of simply offering advice and assistance. This policy established good feeling between the people and the authorities and at least checked the ravages of the disease. Only 7.5 per cent. of the houses disinfected during 1901-02 had cases of plague in 1902-03, but of 51 infected houses which escaped disinfection 43 showed return cases of plague. In the last season's work in only 0.5 per cent. of disinfected houses did cases recur within the next ten days, and in 0.4 per cent. after ten days. The people are beginning to learn in the dear school of experience the lesson to evacuate their villages as soon as plague appears or as soon as rats begin to die.

The Anti-Malaria Campaign.

The Liverpool School of Tropical Medicine has just issued a most important and practical paper on the prevention of malaria in the tropics. In 1902 the school sent an expedition to the Gambia, which was conducted by Dr. Dutton. Malaria was found very prevalent in the colony. Of the native children examined 80 per cent. harbored malarial parasites in their blood. The liability of infection of Europeans occurred soon after the rains were established, and lasted up till the end of November. Mosquitoes were found to be largely bred by white men on their premises. In one factory yard 6 barrels, 17 tubs and 8 small wells were found to be breeding places of culex, stegomyia and anopheles. During the dry season, November to May, there are no natural breeding places for mosquitoes in Bathurst. The people breed mosquitoes solely on their own compounds. A crusade against mosquitoes has been inaugurated. One hundred and thirty-one cartloads of old tin pots and other rubbish have been removed.

Correspondence.

The Work of Mr. Robert Jones.

LIVERPOOL, July, 1903.

To the Editor:

Liverpool is known to everyone interested in the treatment of deformities as the home of the late Hugh Owen Thomas, whose original and practical mind has left an indelible impression on surgical technics. Carrying on the work in the same building, and inspired by at least an equal enthusiasm, his gifted nephew and successor, Mr. Robert Jones, is conducting one of the most remarkable orthopedic services in existence. This work is well known to specialists, but must be seen to be appreciated, and as it was the writer's privilege, through Mr. Jones' courtesy, to observe the work for several days, these impressions have been jotted down with the feeling that it deserved to be more widely known among the profession at large.

Mr. Jones begins his day after an early breakfast by visiting his patients at their homes or in the various private hospitals where they have been placed. About 11 o'clock he returns to his office, where he passes quickly from one patient to another in the various rooms, spending but a moment with each, but seizing at once with an almost intuitive instinct the nature of the affection and the essential indication for treatment. Small operations, such as tenotomies and mobilization of adherent joints, are often done on the spot, his lively optimism and cheerful tact being in many cases the only anesthetic employed. Sinuses are dressed, fractures splinted, apparatus applied and joints *x*-rayed by several experienced associates, and soon the place is a veritable hive of interested activity, a hopeless labyrinth to one without the clew. A dozen cases are started, none are finished, patients crowd the rooms and wait in corridors and closets, everything to the outsider is hopeless confusion, but one thread after another is picked up by the busy master, one difficulty after another solved on the spot, order is brought out of chaos, and in an incredibly short space of time, each patient had had the proper diagnosis, and the proper treatment applied, and has been instructed about home management and when to call again.

This attempt at a description is a sober, but inadequate, account of what actually takes place. The means used are of the simplest description: five or six types of simple soft steel

supports are used for the ordinary cases, and various sizes of these are kept in stock, so that relief may usually be had at the first visit; these supports are made on the premises, the dressings are as simple as the splints. An orthopedic instrument maker is always in attendance to take orders for more elaborate appliances when needed; no plaster of paris is used. The more serious operative cases are referred to one or another of Mr. Jones' hospital services.

The writer has never seen anything approaching this mastery of the clinical material or of the technical means. This was equally displayed in the work at the Royal Southern Hospital, where Mr. Jones has a surgical service. On his regular operating day, Wednesday, he often exceeds twenty operations. On the Wednesday at which the writer was present he did twenty-six; beginning at 2:30 p. m. he finished at 9:30, doing every operation but one himself, which was done by the house surgeon. The operations were done on a table, which was also used as a stretcher, and by having two of these stretcher-tables and two anesthetists, the operations followed each other with almost clocklike punctuality at an average interval of fifteen minutes, and without any appearance of haste. When one considers that this included dressings in most cases, and that there were three knee resections, and other operations of equal importance, the performance seems little short of marvelous. All the operations but one were undertaken for the relief of deformity or joint disease. Among those of special interest were the excision of large pieces of the adductors of the thigh for spastic paraplegia, excision of the peronei for persistent peroneal spasm, excision of a large diamond of skin from the front of the arm and forearm, with suture of the edges for flail-elbow, excision of a wedge of bone from the top of the foot for severe paralytic pes cavus in an adult, correction of knock-knee and of a hip deformity, the section of the bone being made with a modified Adams' saw, arthrodesis of the ankle with removal of a wedge of bone for paralytic calcaneo-valgus, and several cases of club-foot and flat-foot corrected by the Thomas wrench, in the use of which Mr. Jones is exceedingly expert. Here, also, no plaster was used, simple adjustable splints being in readiness to hold the part in its corrected position. Many of the club feet and rhachitic deformities were sent home the same day.

Here, as in the office practice, the striking thing was the clear and quick appreciation of the gist of the matter in hand, and the instant application of the simple and effective remedy. Another striking feature of the work was the hearty and intelligent co-operation of his associates. Mr. Jones has attracted to himself a group of young men of skill and experience, who vie with each other in their devotion to him and to the work, and whose team play, if I may use the expression, is remarkably effective; there is no question of precedence, the right man is always on hand to do the right thing in the right way. The spirit of the place is as fine as the work and personality of the master. Owing to Mr. Jones' approaching vacation the writer was unable to see his regular Saturday out-patient clinic at the hospital or his free Sunday at the office, where he treats some 7,000 cases on the alternate Sundays of a year, but enough was seen to make an impression that can never be forgotten. HENRY LING TAYLOR.

The Transmission of Yellow Fever.

NEW YORK CITY, Aug. 11, 1903.

To the Editor:—On my arrival from Cuba I perused with great interest the article of Dr. James Carroll on "The Transmission of Yellow Fever," published in THE JOURNAL, May 23, 1903, the replies made to it by Drs. Carlos I. Finlay and Aristides Agramonte, both of Havana, Cuba, and Dr. Carroll's last rejoinder.

I wish briefly to state a few facts on the matter discussed by pointing out the principal differences between the experiments of Drs. Finlay and Delgado, on one side, and the Army Yellow Fever Commission on the other. The contrast is truly remarkable, and fully explains the point in question.

Finlay and Delgado were trying to find in the *culex* mosquito a prophylactic agent by means of which they could make non-immune persons immune to yellow fever, very much as it happens with the vaccine virus against smallpox; and the army commission were trying with the *Stegomyia fasciata* mosquito to produce true yellow fever with all its dangers and natural virulence.

Finlay and Delgado claimed they found that in from two to six days the contaminated mosquito causes an attenuated attack of the disease (the so-called "acclimation fever") which renders immune the person so bitten. The Army commission found that in that space of time nothing at all happens to the person so treated, and that it requires a lapse of from twelve to seventeen days, or longer, for the mosquito to transmit genuine yellow fever, not acclimation fever.

Finlay and Delgado did not say to what sex their culex mosquito belonged. The Army commission distinctly stated that it was the female *Stegomyia fasciata* mosquito, and only the female that transmits yellow fever.

Finlay and Delgado declared that the culex mosquito was one way in which yellow fever can be conveyed from a sick person to a healthy non-immune, leaving to be supposed that the disease might also be transmitted by other means. The Army commission emphatically asserted that the female *Stegomyia fasciata* mosquito is the only and exclusive means by which yellow fever is transmitted from one person to another.

Finlay and Delgado had no idea of exterminating mosquitoes because they wanted them, as a prophylactic agent to render immune the persons liable to get yellow fever. The Army commission clearly and distinctly demanded the extermination of mosquitoes because they were the true agent of propagation of yellow fever. To such a point the army commission affirmed this as to state that "in the absence of the mosquito the yellow fever patient is harmless."

If we are to judge a scientific medical discovery by the statistics presented in its favor, Dr. Carlos I. Finlay has no reason to claim the discovery of the transmission of yellow fever by mosquitoes. He is perhaps entitled to the suggestion, although some claim might be made in favor of Dr. Josiah C. Nott, Mobile, Ala., who in 1848 published an article on "Yellow Fever Contrasted with Bilious Fever. Its Mode of Propagation and Probable Insect or Animalcular Origin," but nothing else.

Out of a total of 87 persons inoculated by mosquito bite by Finlay, he obtained one case which presented a mild albuminuric attack, thirteen cases in which only "acclimation fever" occurred, and seventy-three negative results.

It is true that since then Dr. Finlay has changed his former opinion, as Dr. Carroll well said: "The original theory of Finlay has been variously modified by him from time to time to meet possible contingencies."

A. M. FERNANDEZ YBARRA, M.D.

The Turning Down of the Old Practitioner.

PLYMOUTH, IND., Aug. 8, 1903.

To the Editor:—I notice in THE JOURNAL, Aug. 8, in the report of the Ohio State Board of Registration, that candidate 172, graduate of Columbus Medical College, class of 1878, failed with a per cent. of 65 5/9, and, in fact, all who failed are old graduates with the exception of one, and that one a foreigner. All who passed are graduates of recent date. Now the physician who graduated in 1878, with about a quarter of a century of practical experience to his credit, ought not to be turned down by the Ohio board, or any other state board, and state reciprocity should be so arranged that a physician licensed by the state in which he practices, and endorsed by the medical profession or county or state medical societies, should obtain a license to practice in any state on presentation of his state license and recommendation by the secretary of the state board of medical registration which issued that license showing that he is in every way eligible for registration.

The trouble with the so-called reciprocity is that it has too much red tape. A physician who can legally practice in one state ought to be legally able to practice in another state

without having to submit to the indignity of a technical examination before a board who are not appointed for their qualifications, but for their political influence.

A licensed physician in any state should be able to practice in any state or territory that is under the American flag, and any physician who has legally practiced continually for ten years or more ought not to be questioned regarding his capabilities, but should be considered competent and recognized as such.

T. A. BORTON.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PERSISTENT HEMORRHAGE DURING AND FOLLOWING OPERATION.

MANILA, P. I., July 9, 1903.

To the Editor:—1. In cases of non-coagulability of the blood where an operation has been begun for, say, cholelithiasis, is it possible to arrest the hemorrhage from the incised abdominal muscles, the abdomen not having been penetrated?

2. What would be the proper procedure when excessive oozing is encountered from the incised muscles in a case of operation of cholecystotomy where there had been no penetration of the abdominal cavity—to stop the operation or to enter the abdominal cavity and then, by means of sutures of the cut muscles, stop the hemorrhage?

3. Are deaths common from hemorrhage in cases where only the muscular tissue is involved, such as in an incision for reaching the liver or its adnexa without penetration of the abdominal cavity?

H. W. Y.

ANS.—1. Non-coagulability of the blood and persistent hemorrhage are not necessarily associated conditions. In hemophilia the blood may coagulate firmly after it leaves the vessels, yet fatal oozing occurs from even a slight wound in spite of all effort to prevent. Fatal hemorrhage from persistent oozing has also followed operations on the gall tracts in the presence of jaundice, also in leukemia. The question of whether the incision penetrated the abdominal cavity or only extended part way through the wall would not influence the question of hemorrhage.

2. This question does not admit of a categorical answer. The judgment and experience of the surgeon in charge and the nature of the case would have to determine the best course to pursue.

3. Deaths from hemorrhage in cases mentioned are not common, but may occur in the conditions mentioned in answer to Question 1. The depth of the incision, whether it extended completely or only partially through the abdominal wall, would not influence the result.

State Boards of Registration.

The District of Columbia Board of Medical Supervisors report by Dr. Wm. C. Woodward, secretary, that at the examination held at Washington, July 9 to 14, 1903, the number of subjects examined in was 17; total written questions, 80; percentage required to pass, 75. The examination was partly oral and partly written. There were 25 examined, and 23 passed:

Deaths.

Andrew Russell Barbee, M.D. University of Pennsylvania, Philadelphia, 1851, Point Pleasant, W. Va., died, August 51, from heart disease, aged 76. He was surgeon in the Confederate service during the Civil War, member of the state senate, president of the U. S. Board of Pension Examiners, secretary of the State Board of Health, etc. While in the senate of West Virginia he was the author of the bill regulating the practice of medicine and surgery, and that creating the State Board of Health.

Thomas J. Yarrow, M.D. University of Pennsylvania, Philadelphia, 1861, died at his home in Philadelphia, August 6, as a result of an injury sustained when thrown from his carriage last October, aged 63. He served in the Union Army during the Civil War.

William H. Amiss, M.D. University of Pennsylvania, Philadelphia, 1853, died at Sperryville, Rappahannock County, Va., August 8, aged 73. During the Civil War he was surgeon in the Army of Northern Virginia, C. S. A.

Ernest H. Lueke, M.D. Western Reserve University, Cleveland, 1898, of Cleveland, was drowned while swimming in Lake Erie, August 5, aged 25.

Adolph Cudell, M.D. Western Reserve University, Cleveland, 1898, of Cleveland, was drowned while swimming in Lake Erie, August 5.

J. W. Shaw, M.D. Saginaw Valley Medical College, Saginaw, Mich., 1901, died at his home in Long Beach, Cal., August 1, aged 37.

John N. Wheat, M.D. Western College of Homeopathic Medicine, Cleveland, 1852, died at Austin, Minn., July 25, aged 86.

John M. Trembly, M.D. Miami Medical College, Cincinnati, died at his home in Butler County, Ohio, July 24, aged 73.

John H. Kinyoun, M.D. New York University, 1859, died at his home in Centerview, Mo., July 27, aged 78.

Deaths Abroad.

Dr. Sigmund Fuchs of Vienna died at Borderbrühl, July 28, aged 44. He was professor of physiology and chief of the Institute of Physiology at Vienna. His name is well known by his numerous contributions to scientific literature.

Dr. Immanuel Munk, an eminent physiologist and chief of the Institute of Physiology at Berlin, died there July 31, aged 51.——**Dr. Leopold Fischer,** privat docent of psychiatry at Heidelberg, died July 30, aged 73.——**Dr. Rudolf Trzebicky,** professor of surgery at Cracow, died there July 22, aged 42. ——**Dr. J. Bougle,** one of the younger set of medical men and journalists at Paris, son and grandson of physicians, died there, July 20, aged 35. He was a collaborator on the *Archives Gén. de Médecine*, and had recently published a large work on the surgery of arteries, veins, lymphatics and nerves.

Dr. Nocard, the famous bacteriologist, professor at the veterinary school at Alfort, France, of which he was the chief for several years, died there August 1, aged 53. His last prominent appearance was at the Antituberculosis Congress at London, where he maintained his views in regard to the transmissibility of bovine tuberculosis to man, combating those advanced by Koch. Nocard's communications to the *Académie de Médecine* and to scientific journals have been important contributions to our knowledge of human and animal pathology and the relations between them. He died after a brief illness, in the midst of active work.

Dr. W. S. Playfair, one of the best-known obstetricians and gynecologists in Great Britain, died, August 13, at St. Andrews, Scotland. He received his degree of M.D. from Edinburgh in 1856, but possessed many other degrees and qualifications, both ordinary and honorary. His text-book on obstetrics has been one of the standards in Great Britain, and his numerous other contributions have maintained his reputation. He has held many high honorary and other positions in his own country, and has been the recipient of high honors from foreign countries. His reputation as a medical teacher was high; he was long connected with the chair of obstetric medicine in King's College. Beside his several obstetric works, which have gone through many editions, he was co-editor with Prof. Allbutt of a "System of Gynecology" published in 1896, and of numerous papers in medical journals, including some on subjects not directly related to his specialty. He is remembered as having had the unfortunate experience of being mulcted $60,000, in a suit a few years ago. It hardly seemed to the medical profession that justice was done him in that case. Of late years he has been less conspicuous, but his death leaves a notable gap among the prominent physicians in Great Britain.

Book Notices.

A Reference Handbook of the Medical Sciences, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume VI. Illustrated by Chromo-lithographs and 763 Half-tone and Wood Engravings. Cloth. Pp. 1004. Price, $7.00 per Volume. New York: Wm. Wood & Co. 1903.
